An Address

ON

THE GROWTH OF CANCER.

Delivered in opening a Discussion on Cancer before the Medical Society of London on March 13th, and before the Medico-Chirurgical Society of Glasgow on March 24th, 1905.

BY E. F. BASHFORD, M.D. EDIN.,

GENERAL SUPERINTENDENT OF RESEARCH AND DIRECTOR OF THE LABORATORY OF THE IMPERIAL CANCER RESEARCH FUND.

PAST NEGLECT TO INVESTIGATE HOW CANCER GROWS.

MR. PRESIDENT AND GENTLEMEN,—I propose to refer more especially to the growth of cancer. The study of the mere processes of growth as distinct from the genesis of cancer has received serious attention from the outset of our investigations and it will be entirely advantageous if others can be persuaded that an attack on this difficult subject can no longer be avoided, as it has been in the past. The undefined amount of the growth of cancer—which term I take to be synonymous with "malignant new growth"—has forced it to the forefront in the course of the experimental investigations of the Imperial Cancer Research Fund. The biological problem presented by the amount of growth has not hitherto been properly appreciated, even by those investigators who, like Jensen, Borrel, and Michaelis, have successfully propagated, carcinomata. In the study of cancer in man, the other clinical and pathological features mask those of mere growth. *By means of artificial propagation we have produced such enormous masses of tissue that the ceaseless cell proliferation has become the most impressive feature, and as the work has progressed the local nature, the infiltrative character, the absence of constitutional disturbance, the relative independence, and the formation of metastases have assumed a different perspective. That the amount of growth which suffices to kill a patient is infinitesimal as compared with the indeterminate total of growth as revealed by experimental propagation is a side issue, however important it may be. *The problem which demands solution is, Why is the growth of cancer limitless?* This concrete and hitherto unknown problem is thrust upon us by artificial propagation, which also *provides* us with a means for experimentally solving it.

It can hardly be claimed that the necessity for comprehending the nature of this undefined growth has been elevated to prime importance in the past; for it has not been made the starting point of any one of the hypotheses which have been advanced from time to time to explain cancer. [illegible]

[illegible] tion of which naturally followed from the nature and origin postulated. The cells of a malignant new growth have been supposed to proliferate because, e.g., they were asserted to be freed from the restraint of connective tissue or liberated from the control of the other members of the cell community by "solution of organic continuity," or because they were derived from "embryonic rests," or were modified reproductive "gametoid" (reduced) tissue, or because a parasite made them multiply. I do not wish to ridicule any one of these hypotheses. I desire, however, to make clear the nature of the assumptions which have been supposed to [illegible] o emphasise that all these [illegible] in common: they postu- [illegible] re for cancer and fail to [illegible] ll multiplication is main- [illegible] wth have not been deemed [illegible] n formulating any of the [illegible]

hypothesis, quotes von Hansemann, a distinguished pathologist and a critic of the grounds on which the belief in a parasitic etiology is based, and reproaches him for confessing his ignorance of how and why cancer cells possess their unlimited powers of growth and for excusing himself both from attacking this problem and from attempting to explain the origin and the nature of cancer. It cannot therefore be asserted that the importance of the subject is denied.

It seems strange that if the power of continued proliferation is so prominent a characteristic so little attention should have been given to it by Thiersch, Waldeyer, and Cohnheim, who so materially advanced our knowledge of malignant new growths. The explanation is the simple one that the processes of cell division were little understood by the older investigators who had also little information on fertilisation and on the development and differentiation of organisms to guide them in studying the normal growth of the human body, *and far less still to help them to comprehend growth* in the aberrant form presented by cancer.

Even in recent times pathologists have continued to concern themselves with the mode of origin and the nature rather than with the growth of cancer. This has been partly due to the continued discussion of the evidence for and against the views already enumerated, and the legacy of restricted outlook which has been transmitted to all investigations carried out under their influence. It has also been due to endeavours to find better substitutes for the old hypotheses, but always on the basis of experience limited to cancer *in man; for the only important contributions to the* discussions on the nature of cancer have been provided by medical men or biologists who have studied malignant new growths in the form in which they come under observation in the operating and post-mortem theatres. Thus studied cancer is almost always already fully developed. The stage at *which it has arrived is alone presented for examination. The* stages through which a tumour has passed, and those through which it will pass, are alike left to the imagination and are supplied in accordance with any hypotheses which may find favour. The limits of objective observation do not extend beyond the stage at which a tumour has arrived and it has been truly said that even the margins of a fully developed and growing cancer yield no information as to its origin. In this connexion, however, it is important to remember that the histological features, especially the direction in which the cells tend to differentiate, are strong arguments in favour of the view that malignant new growths develop from cells of the normal tissues. These arguments grow in force when regarded objectively and free from the bias of the Cohnheim hypothesis which postulates an embryonic and atypical character for the cells of malignant tumours. Deviations from the typical character of the cells of the tissue "mimicked" are frequent. They are, however, of much less importance from the standpoint of investigation than the universal occurrence of a single differentiation when *any is* present and *the occasional* manifestation of all the features of malignancy by growths which show the most perfect differentiation and even exhibit the exercise of the secretory function of the tissue represented.

Investigation of cancer in man is so limited in its scope that it is not surprising if general credence has been given to the belief that it will be impossible ever to observe a cancer *in process of* formation and pathologists have in consequence remained content to modify the old explanations or to postulate anew other modes of origin whenever a previous conjecture has been shown to be untenable. All that could be ascertained by the study of human cancer appeared to have been elicited, new facts were not forthcoming, and new explanations of the old facts did not have even the appearance of an advance. Is it surprising that pessimistic views obtained ascendance and that medical men only cognisant of the seemingly insuperable difficulties presented by the study of cancer in man should declare that its nature can only be elucidated with the explanation of life itself? The method has been at fault. The investigator has been poking about in a corner and the narrow scope of his inquiries has prevented him from forming a true conception of the problems and from making at the outset even a preliminary survey of the general features of the field of investigation. The study of cancer has been pursued not in a rational way but empirically and the pessimism which has resulted from failure is logically ascribed to the methods which have been employed and not at present to the

FEATURES OF SPORADIC GROWTH.

The first essentials to the rational study of cancer are facilities for subjecting any hypothesis to the test of experiment and freedom from the restrictions which circumscribe its study in man. Hence it came to be one of the first duties of the Imperial Cancer Research Fund to determine the extent to which malignant new growths occur throughout the animal kingdom. These investigations, augmented by the results of other workers, have shown that if allowance be made for the differences in anatomical structure of the various animals the problems of cancer present the same essential characteristics throughout the entire vertebrate phylum. This identity in nature—which, of course, involves identity in the character of the anatomical lesion upon which the diagnosis of malignant new growth can alone be based—is a matter of prime importance. It yields a secure comparative basis for deduction and puts out of court as direct causative factors many external agencies which demand consideration in the higher forms of life and of necessity attract attention in the case of mankind living under the artificial conditions associated with a high degree of civilisation. The information elicited by studying the growth of cancer in the comparative and experimental manner thus rendered possible must be brought to bear upon the nature of the disease in man and reviewed in the light of the knowledge which has accumulated during many years of clinical and pathological observation. The boundless cell proliferation proceeds with an energy which is only comparable with the initial proliferation in embryonic tissues; nevertheless, it is intimately associated with another main feature of the disease—viz., its increasing relative frequency as life advances. This is technically known as the "age incidence" of cancer and must be explained before any claim to the establishment of the sufficiency of a hypothesis can be set up. All the well-known hypotheses, however, break down before the problem of the "age incidence" of cancer and it does not necessarily follow from the primary assumptions which underlie any one of them. The comparative study of sporadic malignant new growths has proved that they occur in animals also with increasing frequency as age advances, both in species with a long and with a short duration of life. They appear in considerable numbers in mankind after from 45 to 50 years, in the horse after nine years, in the dog and cat after nine years, in the trout after from five to seven years, and in the mouse after two years. The higher incidence manifests itself after an interval which varies in different species in direct relation to the absolute duration of life. The interval of relative freedom is in consequence proportionately much the same for different animals. The maximum incidence also coincides with the decline in reproductive activity. This fact has given rise to speculation on the influence of the sexual organs. These speculations are deprived of any significance by the fact that cancer occurs in castrated animals at the same period as in entire animals. Neither the cessation of a normal secretion nor the appearance of an abnormal one can therefore be the cause of the maximum incidence of cancer at this time. The variations in the natural sporadic growth of cancer in different forms of life therefore yield some valuable information and are of sufficient importance to claim further study.

The preliminary stages before the appearance of cancer, which may take 50 or more years in the case of man, are passed through in about two years in the case of the mouse. It would take so long to observe the various stages of the whole process in mankind that it is impossible to attempt it with hope of the practical results which are theoretically attainable in the case of short-lived animals. The relation which exists between the age incidence of cancer and the duration of life awakens expectations of another kind. There are laws which govern the varied but definite growth, which determine the size of body and the length of life in the different vertebrates. May they have a determining influence not only on the time at which the disease appears sporadically but also set time limits to various phases in the development and growth of cancer itself? Just as the gestation period varies from 21 days to nine months in the case of the mouse and human subjects in accordance with the laws which govern their respective developments, so if there be stages in the growth of cancer they may also be adapted to the compass of life in different animals and be gone through more quickly for the mouse than for man. A mankind and the mouse give evidence in their offspring how their own growth has originated, is maintained, and declines, so it has seemed rational to look for evidence of a similar kind in the undefined and apparently continuous growth of cancer. This evidence has been most conveniently sought for in short-lived animals and there also most readily interpreted with the assistance of experiments. Such observations are entirely impossible in the case of man and are not always practicable in the case of animals.

NATURE OF ARTIFICIAL PROPAGATION.

Malignant new growths are said to be physiologically and morphologically independent of the needs of the organism primarily affected. This character of relative independence appears in its highest degree in the successful transference of malignant new growths to new hosts. The power of unbounded proliferation is also most clearly demonstrated in these circumstances. I need not pause to contrast the limited proliferation which follows the transplantation of other animal tissues with that of cancer under the same conditions. The artificial propagation of a malignant new growth by transplantation into a new host of the same species, or into a new site in the case of the organism primarily affected, is attended with difficulties which are not easily overcome. A large number of transplantation experiments have been performed in the horse, cow, dog and cat, all with negative result.[1] In the rat malignant new growths have been transplanted successfully, and in the mouse about a dozen different tumours have been transplanted under the precautions which are necessary to establish the unequivocal nature of the result. In what follows I shall rely mainly upon the details of the experimental observations of the Imperial Cancer Research Fund upon the successful propagation of five different sporadic carcinomata through several generations of mice, and for comparison on the study of the processes which result in the production of large tumours in the case of an infective granuloma of the dog. An unfortunate misconception of the significance of the facts has led to the nature of the experimental propagation of cancer being confounded with that of the infective processes, from which it differs fundamentally. The experimental propagation of a malignant new growth means neither more nor less than the continued proliferation of the cells of one animal in another animal. It may also be practised on the same animal without, however, modifying its significance. The parenchyma cells of the tumours which arise at the new sites are the direct genealogical descendants of those introduced They are not provided by the host. The process is as remote from being of an infective nature as that responsible for the formation of secondary deposits with which it is strictly comparable. What reaction there is on the part of the host is limited to the supply of the vascular and supporting structures which the parenchyma cells—displaying again their independence—have power to make subservient to their needs. The process of infection is wholly different. The cells of an infective granuloma introduced at the time of inoculation are merely vehicles—living substitutes for the platinum loop—for the conveyance of the infective agent There are infective granulomatous tumours closely resembling sarcomata of which the causative agent cannot yet be isolated and is not recognisable by any method known to us. In these cases also the process of infection which follows inoculation with portions of the granulomatous tissue is identical with that which occurs after inoculation with isolated pathogenic organisms. The introduced tissue only plays the part of a vehicle. It succumbs and is ultimately absorbed and when new tumours result they are entirely composed of the tissues of the reaction on the part of the host. All the stages in the reaction can be traced from the gradual transformation of the elements of the connective and vascular tissues up to a fully developed tumour identical in structure with that from which the original infection was derived.

In the experimental propagation of cancer the elements of the soil play the insignificant part of subserving the needs of the tumour, of which the essential part is genealogically derived from another animal. By these means a part of one animal, often long dead, is kept alive by what is really an artificial circulation provided by another. In tumours which result from infection the only constituents, apart from the pathogenic organisms, are the elements of the soil themselves. Any comparison which may be drawn between the two processes is correctly limited to the differences and similarities which may exist between the nature of the reaction of the tissues of the host when pathogenic organisms or cancerous cells are proliferating in their midst. What we mean by disease is, in fact, the reaction of the tissues of [illegible] ncies of any kind. In [illegible] result in the formation [illegible] artificial propagation of cancer the reaction is a very subsidiary pheno- [illegible] new growths yields conclusive experimental evidence, in keeping with accumulated clinical experience, that cancer *quâ* cancer does not produce specific symptoms of its presence. Malignant new growths have only been successfully transplanted from one animal to another of the same species. The cells of a malignant new growth of one animal are so much out of their element among the tissues and fluids of an animal of another species that they are unable to maintain their vitality. Their fate is probably the same as that of the blood corpuscles of a strange animal when employed in the manner in which transfusion of blood was originally practised in surgery.

---

[1] In the positive cases reported sufficient care has not been taken t

GENERAL FEATURES OF GROWTH IN ARTIFICIAL PROPAGATION.

I have already drawn attention to some of the comparative features of growth in sporadic tumours and shall now briefly refer to some of the phenomena presented in propagated tumours. An attempt to propagate a tumour requires to be carried out under many precautions. Numerous factors have to be taken into account in interpreting the results of [illegible] nerally, the [illegible] ow a grada- [illegible] rcentage of [illegible] percentage and to others again which have given absolutely negative results. The contrast between the tumours at the top and those at the bottom of the scale, therefore, does not imply distinctions in nature, although it signifies that the respective groups differ in the degrees in which they possess the properties which adapt them to the conditions obtaining in artificial propagation. These specific qualities of the cells which determine the short or long duration of life of different species of animals appear to play an important part in the experimental establishment of tumours in a new host and, further, there is also much evidence to show not only that the qualities of the cells of different tumours vary [illegible] at they differ in [illegible] e same tumour at [illegible] tage of successes [illegible] same histological [illegible] in man, for they [illegible] that, in addition to the importance of the site of a primary tumour and the degree of vascularity, amount of movement, and other conditions, which have long been recognised to influence the early or late appearance of metastases (e.g., in the cases of epithelioma of the tongue and the larynx) there is something else of great moment which is inherent—but not always present—in the tumour cells themselves and without which even a suitable soil may remain free from invasion. The surgeon and the pathologist are familiar with the contradictory behaviour of malignant new growths which are reasonably supposed to be identical; how they present variations in malignancy and how with uniform care in operative procedure uniform results are rarely obtained. The inconstancy in the qualities of the cells of the same tumour revealed in the course of our experiments is a contribution to the solution of these apparent contradictions, although it must not be forgotten that we are not yet able to express any definite opinion on the influence of the soil into which tumours are transplanted.

CELLULAR AND INTRACELLULAR PHENOMENA OF GROWTH.

When we turn to consider the more minute processes of growth—the cellular and intracellular phenomena—we [illegible] hat the cells of carcinoma and sarcoma breed true. [illegible] hat any evide [illegible] ion only—tha [illegible] of the cells [illegible] tumour there are several varieties of direct (amitotic) indirect (mitotic) division. The phenomena of indirect division are the more prominent, and different authors have described the various features of the normal bipolar mitosis and several abnormal manifestations of the same process. A not infrequent abnormality is cell division by multipolar mitosis, in which the rods of chromatin are arranged, not on one spindle with two poles, but on several spindles which converge towards a corresponding number of poles. The bipolar and multipolar mitoses as a rule proceed in a way which gives rise to symmetrical figures and distributes equal numbers of the chromatin rods to the nuclei of the daughter cells. However, both the bipolar and the multipolar figures may occasionally appear to be asymmetrical and suggestive of an unequal distribution of the chromatin rods to the different poles. All the chromatin may not enter into the process in other dividing cells, and it is said to be "cast out." The peculiar form of cell division which prepares the reproductive elements for fertilisation has also been described in cancer. This form of cell division presents contrasts to the main features of ordinary bipolar mitosis, from which in the reproductive tissues it is readily distinguished in all its phases. Flemming, therefore, designated it heterotypical. In the reproductive tissues it results in each of the two daughter nuclei receiving exactly half the number of chromatin rods, which an ordinary bipolar mitosis would distribute, and if the daughter cells proliferate the progeny retain the halved number of chromatin rods when in division. The halved number of chromatin rods is only restored to the full number when that fusion of nuclei occurs which is the one constant feature of fertilisation. We have pointed out that the cells which exhibit heterotypical mitoses in cancer differ from cells undergoing this process in the reproductive tissues. The differences extend also to the preparations for division and to the stages which follow it.

The various deviations in cancer from what is looked upon as the normal course of cell division are not exhausted by the above catalogue. There are other irregularities. Many dividing cells possess less than the proper number of chromatin rods, it may be half or less or more than half this number, others have too many. These two groups of nuclei were named respectively hypochromatic and hyperchromatic by von Hansemann. The hyperchromatic nuclei arise by preparation for a cell division which is, however, omitted and perhaps also in other ways. The hypochromatic nuclei may arise by multipolar or by asymmetrical mitoses, by casting out of chromatin, or by the heterotypical mitosis. It is not possible to tell by what method a cancer cell which is dividing has come to possess too few chromosomes, even should they be exactly half as numerous as they ought. There is thus a confused series of normal and abnormal phenomena going on side by side. With one exception all the abnormal phenomena have been shown to occur—although they are less frequent—in the processes of chronic inflammation, in benign tumours and elsewhere; but sufficient time has not yet elapsed to permit of a proper estimate of the significance of the heterotypical mitosis in cancer.[3] We have already stated that it is not a constant feature of malignant new growths; indeed, it may be entirely absent when the anatomical and pathological features of malignancy are present in man, or, on the other hand, be present in the absence of the latter.

All attempts to unravel the confusion of cell division in sporadic tumours have failed to pick out the essential from the negligible phenomena. If our knowledge of how the growth of cancer is maintained is to advance the hitherto unsurmountable difficulties presented by the disorderly phenomena of cell division must be overcome. In artificially propagated tumours the difficulties fortunately give promise of being more easily surmounted. Our long-continued observations on many generations of transplanted tumours have yielded the valuable results that a tumour maintains unaltered its general histological characters under the longest propagation yet attained and also the minute cell characters, including the nature of the differentiation and that constant number of chromosomes which is normal to the tissues of a healthy animal. Cell proliferation proceeds throughout all generations by typical bipolar mitosis. The various forms of irregular cell division which are such striking features of sporadic tumours do not occur and the process of proliferation becomes orderly. There can be no question of the proliferating cells showing too many or too few chromosomes. A hypochromatic nucleus, even one with exactly half the somatic number of chromosomes, is such a rarity that we have not yet seen one. Yet at recurring intervals, which coincide with the reappearance of other phenomena, the heterotypical mitosis is found distributing half the normal number of chromosomes to the daughter nuclei. Since in all other dividing cells the normal number of chromosomes is retained, it follows that if the heterotypical mitosis is anything more specific for cancer than the other irregularities present in sporadic tumours it must be an essential phase intercalated in the process of growth. Fusion of the daughter nuclei would be necessary to restore the normal number of chromosomes and might be expected to establish powers of proliferation and of relative independence such as follow the nuclear fusions of fertilisation, and to result in behaviour similar to that of an organism of a succeeding generation towards the one which has preceded it. Otherwise the heterotypical mitosis can only be an incident by the way in a continual vegetative proliferation by normal bipolar mitosis. If the first interpretation is correct then the apparently uninterrupted growth may be further analysable. We may then expect it to be a discontinuous process maintained by an orderly series of cell changes and the explanation of the stages through which the cells of fully developed tumours pass in the incessant renewal of proliferation will indicate the nature of the changes which set the growth agoing.

We can form an opinion of the stage at which the heterotypical mitosis will be intercalated in the growth of cancer. In animals and plants this mitosis marks a terminal phase in cell proliferation and ushers in the preparatory stages for the sexual production of a succeeding generation. It is permissible to draw an analogy with cancer and to interpret the heterotypical mitosis there as a terminal phase of growth, a view which is strengthened by the occasional occurrence of this peculiar form of cell division in the chronic proliferative changes of superficial glossitis in elderly individuals. In the artificial propagation of Jensen's tumour we have only been able to convince ourselves of the occurrence of the heterotypical mitosis at definite intervals and then always in association with other recurring phenomena, notably the establishment of intimate secondary connexions between the nuclei of adjacent parenchyma cells. The occurrence of the heterotypical mitosis in chronic superficial glossitis may be legitimately correlated with the truth that the cells of malignant new growths are endowed with powers of differentiation in one direction only, which has hitherto been the most powerful argument we possessed in favour of the opinion that a cancer arose in the tissues of the primary site the structure of which it imitated. It will be obvious why cancer need not always follow upon the final stages of cell multiplication but only when the process of nuclear fusion has been properly consummated, to secure which there is no special mechanism, and consummation is therefore attained even more rarely than in the case of the sexual elements, to secure the union of which one is provided.

Attention has been drawn to the fact that all hypotheses in explanation of the origin and nature of cancer break down, not only in not explaining how growth is maintained but also before the problem of the peculiar age incidence of the disease. Several investigations have shown that time limitations modify the fundamental features of cancer in an important way. The effects of time cannot be explained on the assumption that the growth of cancer is uniform and continuous. They harmonise with the features of a form of proliferation which is incessantly renewed and therefore support the cytological observations. The relations which exist between time and various features presented by cancer all bear upon the explanation of the increasing frequency of the disease as life advances. Different but definite limits are set to the rate of growth, to the size of the body—i.e., total amount of growth—and to the duration of life in man and animals. A parallel can be drawn between those specific characters and the equally specific age incidences of cancer. They are all dependent on factors innate in the different forms of life and the time when malignant new growths appear is as much determined by the biological laws peculiar to each species of animal as are the form of the body and the absolute length of life.

The span of life of the individual is not the same as that of the separate organs and tissues which have contributed to its maintenance. Some organs and tissues early attain full development and disappear; others are only active during adult life; and others, again, as long as life lasts. The age incidence of cancer in different organs presents contrasts similar to those found in species with long and short lives. Other factors, however, greatly modify the mere influence of time and we do not perceive in the organs of an individual the sharp distinctions exhibited in the representatives of different species. There are, however, indications of such differences. To take only one or two instances from human pathology, the chorion has a short life and chorion epithelioma appears at an interval after fertilisation which corresponds to its old-age stages of proliferation. The mamma and the uterus attain maturity more slowly and are active for a relatively longer time but carcinoma has its highest incidence when the organs are undergoing involution. The skin remains functional long after middle life and the age at which squamous-cell carcinoma is most frequent corresponds. As the compass of life determines the general incidence of cancer in a species, so also the same factor helps to determine the occurrence of malignant new growths in different sites in any one animal. The age at which the maximum incidence of cancer occurs in any one species results from the combined action of the factors which have been discussed; but at special sites there may be contributory causes whereby the final stages of proliferation are attained more early, where, e.g., chronic irritation or injury has led to excessive cell multiplication. All the many modifications which time limitations effect on the characteristic features of cancer support the conclusion from the experimental and cytological observations; and the view that the unbounded growth of cancer follows on the terminal phases of normal cell multiplication in consequence of nuclear fusion makes the age incidence of the disease a necessary consequence.

The provisional working hypothesis based on the study of how cancer grows requires no subsidiary assumptions to explain all its other features. The circumscribed nature of the primary area, or areas, the relative independence of malignant new growths, their power of continued proliferation, their destructive and infiltrative character, the formation of metastases, the peculiar age incidence, the single differentiation, transmission with all its limitations, the absence of a specific symptomatology, and the addition of malignant growth to congenital tumours, are all naturally explained if it be true that the cells of the body and embryomata tend sometimes in the final stages of proliferation to undergo changes which prepare them for nuclear fusion which is occasionally consummated. These investigations are still proceeding on other tumours of different character and no claim whatever is made to finality in laying before you some provisional conclusions which must stand or fall in accordance with the results of future experience. At present these provisional conclusions possess the great value of stimulating us in our study of a very difficult and involved subject and of assisting us to devise means for experimentally attacking it. I may now briefly summarise the main results of the investigations.

1. Cancer is identical in all vertebrates and in growing accommodates itself in a striking manner to the time limitations imposed by the compass of life in different animals.

2. Under favourable experimental conditions the growth of cancer is undefined, of enormous, and, so far as we can judge, limitless amount.

3. Artificially propagated cancer displays all the characteristic features of the growth of sporadic tumours.

4. The growth of artificially propagated cancer is due to the continued proliferation of the parenchyma cells. We have confirmed this conclusion, originally advanced by Jensen, on his own tumour and on four other different carcinomata.

5. The artificially propagated parenchyma makes the reaction of the host subserve its own needs.

6. Artificially propagated tumours cause no symptoms in the organism to which they have been added.

7. The power of differentiation is definitely in one direction only, even three and a half years after separation from the original host.

8. The number of chromosomes constant for the healthy body tissues is retained, notwithstanding the recurring reduction of this number to the exact half.

9 The balance of evidence is in favour of the growth [illegible] form and continuous [illegible] therapeutics the investigations [illegible] rch Fund thus far establish the early surgical treatment of cancer and of the conditions suspicious of cancer, upon that experimental and rational basis which has hitherto failed Artificially propagated tumours produce metastases as do sporadic tumours Sufficiently early removal of the local transplanted tumour removes metastasis from the region of possibility and the immediate practical outcome of the whole investigation is a strong experimental justification of early operation in cancer We have made many attempts to modify the growth of propagated tumours, they have been, however, purely empirical and must continue so until the fundamental problem which I have outlined has been solved

We have certainly not ascertained all the truth and it would be rash to forget that the positive experimental results are at present based upon observations in mice only This may be too narrow a basis and I must therefore protest that I do not appeal to you in support of any hypotheses explanatory of the nature and origin of cancer but simply in advocacy of the necessity for further investigation into how cancer grows in the hope that we may determine why it grows I have laid before you a provisional interpretation of the few isolated observations we have made thus far, with the conviction that it is capable of being tested by investigations now progressing and this is a very different matter from taking refuge from criticism in a postulate which cannot be submitted to objective investigation

The Milroy Lectures

ON

INDUSTRIAL ANTHRAX.

Delivered before the Royal College of Physicians of London on March 7th, 9th, and 14th, 1905

BY T M. LEGGE, M D OXON, D P H CANTAB,

HIS MAJESTY'S MEDICAL INSPECTOR OF FACTORIES

LECTURE III[1]

Delivered on March 14th

MR PRESIDENT AND GENTLEMEN—To follow the incidence of anthrax on the workers in the different processes in the three main industries concerned, wool horsehair, and hides and skins it is only necessary to remember the following points In the case of wool, with the exception of Van mohair, the material is unwashed until after the fleeces are opened to examine their condition, sorted according to colour and quality, cleansed from dust in the willow machines, and blended in large heaps to obtain a uniform shade of colour in bulk. Dust is inseparable from each operation It next passes through three separate tanks or wash bowls containing soap solution kept at a temperature of about 130° F, so that the effect of washing may be expected to lessen the risk from anthrax in the later processes after drying—namely, carding, combing, finishing and gilling—to which it is subjected prior to spinning In considering danger from horsehair distinction must be made between the short mane hair to be curled for stuffing purposes and the long tail hair to be woven into hair cloth and, again, between material that is dyed and that which is undyed Were all material dyed I believe that the incidence of anthrax in the industry would be materially lessened because for this process to take effect the hair must be left for some hours in the dyeing solution heated by passage of steam through it Although in the trade this process is described as "boiling" it is rare for a temperature of 212° F to be reached throughout the solution Dirt, however, is mechanically removed and probably the virulence of the anthrax spores is diminished Specifications unfortunately require at times that horsehair shall remain undyed and shades of a grey colour are demanded Manufacturers allege that to obtain these grey natural colours material must be used from countries like Siberia in which anthrax is rife Be this as it may, frequently all the early dusty processes of opening, sorting, willowing to free from dust, and drawing into bundles according to length are done with material that has undergone no preliminary washing process Finally to set the curl the hair is exposed to dry heat at a temperature of 250° F for 24 hours or is exposed to steam under pressure, so that risk after leaving the factory is not worth consideration Long hair for weaving purposes is always soaked in a warm soda solution and danger is minimised, as the process of heckling to separate the individual hairs is done while the material is wet Bristles undergo only a process of dry heckling—frequent drawing of the hair through upright steel pins—before they are used in brush making As a rule they arrive sorted and cleaned except in the cheaper kinds, notably "Chinese riflings," which are of low quality and too short to be properly bundled according to length Large quantities of China mane hair are also used in the manufacture of [illegible] s and this, although it frequently [illegible] preparation in China undergoes [illegible] that described in the case of bristles In hides and skins evolution of dust and consequent danger are greatest in the early process of sorting and throwing into heaps according to quality The precise occupation at which the affected persons were employed is shown in Table XII arranged in the order of the processes of manufacture from the arrival of the material at the factory to the time when it leaves in a finished condition

Anthrax in Relation to the Wool and Worsted Trades.

There is interest in comparing the facts now known of the incidence of anthrax in wool and worsted as regards type of the disease, class of persons attacked, supposed dangerous material, and other circumstances with those brought to light a quarter of a century ago when the disease first came prominently into notice by the report of Mr. J. Spear in 1881.[2] He dealt with 32 cases (21 fatal) which occurred during 11 months, November, 1879, to September, 1880, in the neighbourhood of Bradford. Of these nine were typical cutaneous anthrax (two fatal) and the remaining 23 (19 fatal) fully developed internal anthrax. Internal anthrax was, he wrote at that time, "the form of the disease which is the much more common one, at all events the more commonly recorded one amongst wool-sorters," and if there were added cases which were considered mild or rudimentary attacks of the internal form the fatality would appear correspondingly less. During the six years 1899 to 1904 only six cases of the internal form have been reported and there would thus appear to have occurred a remarkable change in the type of the disease prevalent in Bradford, the external and internal form having changed places as regards frequency of appearance. As to the diminution of internal anthrax there is no doubt. Some explanation of the change may be found in the more frequent diagnosis of external anthrax now but this is insufficient to explain the very great reduction in cases of true wool-sorter's disease. Moreover, mild or rudimentary attacks of the constitutional form of the disease are never reported now. Several of the cases investigated by Mr. Spear followed on manipulation of gravely infected Van mohair. More recent cases of internal anthrax in 1898 and 1899 similarly followed one another quickly on manipulation of badly infected Persian wool. With our knowledge of the greater virulence of the bacillus under certain conditions it is not unreasonable to assume that variations in type may be due to this cause and that at some future time there may be recrudescence of the severer form.

The principal circumstance, however, which has altered since the time when Mr. Spear wrote is that under which the manipulation of the wool takes place. Now, in addition to regulations requiring care in the opening of the bales and removal of the damaged wool or hair, fallen fleeces and pieces of skin, none of the dangerous specified wools (Alpaca, Pelitan, Cashmere, Persian, Camel hair, and Mohair) may be opened or sorted except at a place where a constant draught of air maintained by a fan carries the dust away downwards. While it cannot be said that introduction of exhaust ventilation at the sorting tables has removed the danger entirely, as the table shows, claim can be made that it is a material safeguard. Instances could be cited in which occurrence of anthrax seems to have followed as cause and effect on cessation or impairment of action of this fan exhaust. Changes in type of the disease therefore may be due to these altered conditions of working. 25 years ago Mr. Spear insisted also on the fact that "with rare exceptions only those suffered who were employed in the first manipulation—in the sorting process,"[3] qualified, however, by the statement that "the power of the wool for mischief cannot be said to be exhausted here, for in the combing-room the material may possibly prove infective." For several years later there must have been the same absence of cases among the carding, combing, and spinning hands, for in a Home Office Report in 1897,[4] charged especially with suggestion of remedial measures, the later wool-combing processes are not specially referred to. Since then, as shown in the table, cases have been most numerous in the processes subsequent to the washing of the wool. Had the scope of the earlier inquiry covered a longer period than one year and extended to other industries such as the carpet and felt manufacture, no doubt cases in departments other than sorting would have been found to occur more frequently than was supposed. So frequent did these cases become that regulations were introduced requiring as perhaps the most important provision isolation from other processes and mechanical exhaust ventilation for the removal of the dust in the process of willowing or cleaning of the material. Cases, however, still continue to be more frequent in the rooms where the carding and combing processes are carried on. I say rooms advisedly because personally I believe som perhaps most, of them are due to infection from unwashe wool, because though combing and carding and spinnin are the principal, they are not the exclusive, operatio carried on in them. The wash bowl occupies a portion of th room or is connected by a passage and along this a current air may pass from where the unwashed material is bein treated. In the few factories in which incidence on workers the combing processes has been most frequently observed th absence of separation of the processes connected with washe and unwashed material has been noted. This explanatio is insufficient, however, to account for all the cases arisin during the later processes. In the year 1904, for instanc two persons at least were attacked in factories where no ra material but only finished "tops" (probably of Persian woo were used. These tops must have passed through all th various stages of cleaning, washing, and the minute separ tion of one fibre from another in the combing machines one factory before they were conveyed to the other whe infection occurred.

Although the pulmonary type of the disease was fir noticed in Bradford after the introduction of alpaca an mohair as textile materials in 1837 several deaths occurred later years (1846, 1853-4, 1867-8, and 1874) from manipula tion of these materials[5] the danger from Van mohair (intr duced about 1863) seems to have overshadowed that fro other material such as Persian wool at the time of Mr. Spear inquiry. He gives the following list of foreign wools in th order of their apparent noxiousness as it was at that time co sidered to be: (1) Van mohair, (2) Persian, (3) Camel hai (4) Alpaca, (5) Turkey mohair, (6) Pelitan, (7) Cape mohai and (8) Cashmere. Now the order would be: (1) Persia (2) Turkey mohair, (3) Van mohair, (4) East India (5) Camel hair, (6) Alpaca, (7) Pelitan, and (8) Cashmer Possibly the disappearance of Van mohair from the positio of greatest noxiousness is due to the fact that Va mohair alone is required by the regulations to be washe and sorted while damp if at all. The list does no take account of the amount of the various materials used Danger from East Indian wool which, although very sandy is believed to be exported in a washed condition, does no appear to have attracted attention, no doubt because its us is much larger in the felt manufacture than in the worsted Probably the use of Persian wool has increased since 1880 The explanation why it is so largely in demand arises fro the fact that this breed of sheep is one of the few in whic the wool is naturally of a black, brown, or fawn colou Thus it is stated that in the Chipal breed in the district round Bassorah, Bagdad, and Mosul only 20 per cent. of th flocks contain white sheep, the remainder being black, grey fawn, or brown; and the wool is of a finer quality than tha of other breeds exported from Mesopotamia. With th demand for cloth of khaki colour there is no likelihood of diminution in the supply of this Persian wool. Fresh open ings for its manipulation in the worsted factories are con stantly sought. Thus the consul reporting on the trade o Nanking[6] alluding to the uselessness of trade catalogues i general says: "The only one which appeared to me to hav possibilities in it was addressed by a firm in London makin khaki uniforms. I wrote to the senders pointing out tha as the Chinese army was now being reorganised if they woul appoint an agent in China it might be possible for the to obtain a contract to supply uniforms for the foreig troops."

It is customary to attribute the absence of anthrax fro manipulation of the immense supplies of Australian and Ne Zealand wool to the fact that such wool has a larger pro portion of natural grease or "yelk" in it, the presence o which would tend to stop diffusion of dust. To me thi reason is not sufficient to account for the facts and attribute the immunity mainly (1) to comparatively sma incidence of the disease in animals; and (2) to the pre cautions taken to prevent the spread of disease and to secur proper disposal of the carcass. The existence of simila precautions would explain why the disease is apparentl transmitted so rarely from countries such as the Argentin Republic where anthrax among animals is common. Thu in New South Wales[7] in 1902, "the sheep were free fro disease except some few cases of anthrax and the losses fro it were very slight." In 1901 no outbreaks were reported

The total number of sheep and lambs shorn in 1902 exceeded 25,000,000. In South Australia[8] in 1902 the list of diseases among sheep does not include anthrax. In the report of the chief veterinary officer of New Zealand for 1899 four outbreaks of anthrax are recorded—the first appearance of the disease since 1895.[9]

Still in seeking for means to render safer manipulation of wool and horsehair from Asia the practice of washing the sheep prior to shearing, willowing it from dirt, and discarding the fallen fleeces in the country of origin would be the next best thing to disinfection of the material were that possible by means of steam. This is what some manufacturers would wish to see done and in March, 1903, the chambers of commerce of Bradford, Halifax, and Kidderminster issued a circular letter pointing out the unsatisfactory condition in which Persian wool was received in the country. Nearly every bale is falsely packed—i.e., the fleeces contain locks (inferior wool), skin, fallen wool, and cotton rags, besides soil, sand, dirt, and dust. They urge especially that persons consigning Persian wool should endeavour, first, to keep out of the bales extraneous matter, and, secondly, to pack locks, fallen wool, and skin in separate bales. Any loss on locks sold at lower prices would be more than recouped by higher prices obtained for honestly packed bales. All the evidence shows, however, that wool is washed less frequently before shipment than it used to be. Thus in 1869 158,000 bales of greasy unwashed wool were sold as compared with 681.500 in 1[illegible] the same years being [illegible] scoured wool 114,000 [illegible] diminution in the quantity of washed fleeces is that the extra cost of washing was not made up to the growers by reduction in freight or the slightly increased market price obtained for it in London.[11] Moreover, the users of wools in this country desire to scour the material themselves in the manner most suited to their particular trade and object to scouring carried out in the colonies and elsewhere. In the report of 1897 already referred to the committee expresses the wish that it were possible for H.M. consuls to report anthrax-infected districts so that by the ear-marking of the bales from such localities imported infection might be traced and arrested.

Mr. Spear[12] was informed that it would not be difficult in Constantinople, where the classification of wools from Asia Minor was made, to secure that fallen fleeces should be classed apart. Pressure in this direction by combined action on the part of manufacturers or of the legislature might have the effect on dealers and native growers abroad of making them take steps to keep apart these fallen fleeces or to separate them in Constantinople. This would of course merely shift the risk from the workers at home to those in Constantinople. The difficulties in the way of carrying out such proposals are many. In the absence of official records based on veterinary reports knowledge of anthrax-infected districts would be untrustworthy and such evidence might tend to [illegible] is unlikely that, in the absence of discriminating veterinary reports, the consuls would be in a position to say what bales were infected. The practice, too, of storing wool dependent on the needs of the market, or on fluctuation in price, would equally tend to make such protection illusory. That the matter, however, has not escaped the attention of some of the consuls is apparent from the following quotation from the consular report from Kermanshah in Persia[13]: "In reply to an inquiry as to why more care was not taken in washing and sorting the wool, the Kermanshah wool merchants declared that no skins, cotton rags, or pieces of string were contained in the wool exported by them. They did not wash the wool so well for export as for spinning in the country, as well-washed wool scarcely fetched a better price in Bagdad than the usual wool exported there." If in this country, with all the precautions which are taken to check the spread of the disease and to prevent the flesh of anthrax-infected animals from coming into the market, illicit dealing is still practised and every year carcasses thus infected are found in the meat markets and butchers' shops exposed for sale, what hope is there that in other countries where there are no regulations, where cupidity is not less marked than at home, and where the disease is probably a hundredfold more rife, material good could be achieved by the branding of bales or by reliance on the exclusion of fallen fleeces in the sorting carried on in Constantinople?

The tariff duties of the United States[14] touch on this point by classifying in three divisions the different kinds of wool imported and levying customs dues of varying amounts according to the quality and previous treatment to which it has been subjected. Thus wools of the first class, including that from Bagdad and China and British colonial wool, among others; and of the second class (including camel hair, angora goat, and alpaca) if imported scoured pay thrice the duty; and if imported washed twice the duty they do if imported unwashed. The duty on these wools also is doubled if the value is increased by sorting or rejection of any part of the original fleece, or, again, if it be reduced in value by the admixture of dust or other foreign substance. High duties are placed on any fraudulent attempt to pass an inferior material as of high quality wool. In the inferior wools of Class 3, including South American, native Smyrna, Russian, camel hair, and "wools of like character such as have been usually imported into the United States from Turkey," the classification is based on an increase in the duty on material containing less than 8 per cent. of dirt. These duties apparently have no reference to the prevention of anthrax, nor is it easy to see, apart from pressure from buyers in the United States, what inducement there is for the removal of dirt in the third class when reduction of the amount of dirt to 8 per cent. increases the amount of duty paid. In the first and second classes certainly twice the duty (24 cents per pound) by reduction in value by admixture of dirt would be an incentive to cleaning the wool. That an effect in the cleaning of the wool from China, however, is produced by these duties is shown by the following extract from the report on the trade of China in 1903. "The best wool comes from the flocks of the petty chieftains outside of China proper, who only shear their sheep once a year. The clip is therefore longer in staple and freer from dirt than that obtained from Chinese sheep, which are shorn two or three times a year. All attempts to prevent more than the ordinary amount of dirt which a fleece must collect have proved ineffectual and wool containing 30 per cent. of real estate still continues to be sent down. The cost of carriage is some £1 6*s.* per cwt., and there is quite sufficient dust in Tientsin to render it unnecessary to pay at this rate for transportation thither of the sand of Central Asia. The imposition by the United States of the heavy import duty on wool of 4 c. gold per pound led to its being thoroughly winnowed prior to shipment and although the quantities recently shipped appear to be less than were shipped, say, ten years ago, the actual amount of clean wool which now goes forward is in reality greater."

Wool in Asia Minor is collected annually at fairs in centres such as Bitlis, Djezireh, and Mogoul. The nomad tribes of Kurdistan bring their flocks to be sheared there and the small dealers bring the wool that they have collected in different parts of the country.[15] Hair and hides in China are collected by Chinese agents in the interior. No foreigners deal directly with the seller in the interior. 50 per cent. of the horsehair comes from Mongolia and 50 per cent. from near Mukden in Manchuria. Tail hair is washed by the Chinese in the interior but manes and combings undergo no treatment as the price at which they are sold would not pay for cleaning. Bristles are collected as follows. The pig when killed is placed in boiling water and the bristles are scraped off. They are washed in hot water, dried in the sun, and roughly bundled according to length and packed in baskets. These baskets are sold to the interior buyer who opens, cleans, and resorts the bristles which he sells to the foreigner who packs them for shipment. No disinfectant of any kind is used. Hides and goat skins are sold by gross weight which includes the mud and the dirt. If the demand is great anything having the appearance of a hide or a skin is included; if slight the bundles contain good skins, for the interior Chinese buyer knows that then the foreigner will be particular and refuse bad skins. These will be stored up until the market improves. It is entirely a question of price.

ANTHRAX IN RELATION TO HIDES AND SKINS.

The history of anthrax in this country in relation to hides and skins can be best traced from the reports of Mr. Spear[16] and of Dr. W. H. Hamer[17] on the occurrence of cases in London. Mr. Spear's report dealt mainly with an outbreak in a Bermondsey tanyard which occurred in 1882-83 due to a consignment of bales shipped from Shanghai. In the space of a few months nine men were attacked, of whom three died. Owing to the danger attaching to the manipulation of the bales several were disposed of in Paris and various ports in Italy and subsequently news arrived that seven men, who had handled these hides in Paris, had been attacked, of whom two had died. Dr. Hamer dealt with a total of 90 cases which had occurred between the years 1873 and 1893. In 86 the occupation was ascertained. Of these 63 handled the hides while in the possession of the hide broker and 23 (of whom 15 were tanners) after removal to other industrial premises. Infection was believed to have been conveyed from China hides in 26 cases, from East Indian in 12, from other specified kinds in nine, and in 34 the source could not be ascertained. The later records which have been obtained since 1899 show that, although the area from which infected hides may arrive has been widened, material from China and East India is now, as it was a quarter of a century ago, the principal source of danger. And later information agrees with the conclusion arrived at by Dr. Hamer that infection from wet hides is very rare. In only two out of his list of 90 cases was there suspicion that wet hides were the cause. Apart from the lessened diffusion of dust by the wet-salting process, Dr. Hamer suggests that the presence of moisture would tend to cause the spores to assume the bacillar form in which they would be more likely to succumb. The cutaneous type of the disease has remained the same, evidence of pulmonary anthrax being as absent now as it was in previous investigations. Dr. Hamer found some ground for the hope that substitution of wet for dry hides which the trade appeared to encourage would, if continued, lessen the risk of anthrax to those manipulating foreign hides in London. He gives the figures of the amount and value of dry and wet hides imported in the years 1882 and 1892. I have added the figures for 1902 (Table XIII.).

TABLE XIII.

Year.	Dry hides.		Wet hides.	
	Cwts.	£	Cwts.	£
1882	576,196	2,098,895	614,471	1,645,786
1892	368,191	946,354	541,286	1,138,903
1902	286,334	845,484	661,198	1,595,109

From this it appears that the total consumption of hides remains the same in 1902 as in 1892; the increase in wet hides balances the reduction in dry. I believe, however, that any conclusions drawn from the above figures are illusory, as the amount and value of dry hides imported are subject to very considerable fluctuation in the trade returns from year to year.[18] If, for instance, the figures for the year 1900 are taken the amount of dry hides imported would be found to exceed those even for 1882 by 171,551 cwt. Again, while from Bombay and Bengal respectively in 1900 dry hides to the amount of 279,045 and 217,787 cwt. were imported the figures in 1903 dropped to 5261 and 41,619 cwt. It is instructive to show for each year side by side the number of cases of anthrax in which strong suspicion attached to Bombay and East Indian hides and the varying amounts imported from Bombay, Madras, and Bengal in the same years (Table XIV.). Famine prevailed over large districts in India in 1899 which accounted for the enormous quantities of inferior hides shipped to this country in the following year. China hides are recognised in the trade as particularly dangerous and assurance is freely given that this risk has diminished the trade in them. Thus the outbreak in Liverpool in 1900 was attributed to the first introduction of China hides to that port. No diminution is reflected in the Board of Trade returns from year to year which would point to the fact that if imports are reduced at one port they are increased at another. Thus, the value of China hides was estimated in 1899 at £21,455, in 1900 at £12,907, in 1901 at £11,053, and in 1903 at £17,131. The reduction in 1900 can be accounted for by the increased supply of cheap East Indian hides and in 1901 by the great flood in the Yang-tze valley. In 1903 the amount of dry hides imported from China stands only below that from Russia, Holland (of which much may be Chinese), and the East Indies. Evidence from consular reports leads me to suppose that the supply will be increased with the opening up of fresh treaty ports. Thus the consul at Nanking[19] writes: "The export of goat skins has made steady progress since the opening of the port. The value of the trade in 1899 was only £1800, as compared with £32,840 last year. There is undoubtedly a future in Nanking for this class of goods as the supply in Honan is enormous. The same remark applies to hides as to untanned goat skins." Again, the British commercial attaché[20] at Peking writes: "The export of hides has increased in volume 347 per cent. since 1891. Large as is this increase the export of hides does not begin to compare with that of India where conditions governing the supply are almost the same as in China. In both countries cattle are solely bred for agricultural purposes and it is only when they get sick or die of old age that their hides are available for commerce. The export of skins is also a large and growing one, having increased 457 per cent. in value in the last decade." In a later year he says: "Some 40 years ago skins and wool were only remotely thought of ...... and the skins of goats from Honan and Shanghai, which are all converted into the smart American boot, have gone a long way towards building up the wealth of Tientsin."

TABLE XIV.

Year.	Dry hides imported from Bombay, Madras, and Bengal (cwts.).	Number of cases of anthrax attributed to East Indian hides.
1898	117,805	1
1899	144,749	3
1900	507,131	7
1901	127,464	9
1902	51,301	3
1903	49,677	3
1904	—	2

The hide and skin industry of Germany appears to be greater than that of this country. Thus the number of hides imported into Hamburg in 1903 is stated in the consular report[21] to have exceeded that of Antwerp, Havre, and the United Kingdom combined. Reports of the factory inspectors give no account of incidence on dock labourers or on those manipulating the material in warehouses prior to tanning processes. They have contained every year from 1891 to 1902 references to cases in tanneries but without attempt at complete returns. The number in tanneries and leather factories thus referred to is 65 with 13 deaths—20 per cent. In three tanneries at Kirchhain in 1898 there were 11 cases and in 1902 six. Here sheep skins only are dealt in and of one consignment of 2000 skins 60 were believed to be infected with anthrax. In France information is still scantier than that obtainable in Germany. In the district of St. Denis, near Paris, record of the cases has been carefully kept since 1875 by Dr. Le Roy des Barres.[22] During the years 1875-97 he has seen 72 cases distributed as in Table XV.

[21] Annual Series, No. 3186, 1904.

[22] Annales de l'Hygiène Publique, 1897, vol. xxxviii.

All but one of the 57 cases occurred in the only premises where foreign material was dealt in, although there are at least three other important tanneries. Chauveau[23] describes isolated outbreaks in tanyards at Morlaix and the neighbourhood in which the incidence on eight men and 23 animals coincided with the first use in the district of hides imported from China.

There seems no reason for doubt that anthrax can be conveyed by completely tanned material. Apart from the cases tabulated from tanned hides, where possibly infection may have been conveyed from raw hides present on the premises, anthrax has been conveyed to horses apparently through the harness. Thus two horses contracted anthrax, the lesion in both cases being on the flank where a quite new pair of reins came in contact with the body.[24] Experiments have shown that the tanning fluids are insufficient to destroy the vitality of the spores. Thus Ravenal found spores still virulent after immersion for 224 days in the seven tanning fluids of different strength ordinarily used, nor could he suggest any efficient disinfection of the hides which was not likely to injure them. Houston's[25] experiments demonstrating the presence of anthrax spores in the effluent from the catch-pit of a hide factory show that they must be able to survive also the arsenicating, liming, and other processes. In an outbreak in Wisconsin,[26] America, dried hides were placed in solutions of formaldehyde varying in strength from 1 in 500 to 1 in 10,000. At the end of 11 days the anthrax bacillus was cultivated from the solutions containing from 1 in 10,000 to 1 in 2500. The formaldehyde combined gradually with the hide and damaged the material. Success in this direction has been claimed for certain patent preserving fluids of one of which it is reported that anthrax spores are killed in hides and skins soaked for an hour in a 4 per cent. solution. Houston[27] has, however, tested [illegible] During the outbreak in Liverp [illegible] of soda was recommended and [illegible] after as well as before its use. An order of the German Government, dated May 9th, 1902, describing the precautions to be taken in manipulating certain hides, states that no method of disinfection is known which is at the same time certain in its action, easily carried out, and not injurious to the material. Obviously to be of real benefit disinfection of hides if practicable should be done before the material is opened in the warehouse where most of the cases occur and to secure this is impossible at present. In this country consequently the precautions adopted in handling hides and skins coming from China and East India are slight, and directed solely to protection of the workers' clothing by overalls, of their food by prohibition of meals in rooms where the above-named hides are manipulated, provision of washing accommodation, and simple means for dressing wounds. A brief summary of the symptoms of the disease and the necessity for prompt attention are also given.

ANTHRAX IN RELATION TO HORSEHAIR.

The occurrence of cases in a hair factory at Glasgow in 1878,[28] described by Dr. J. B. Russell, first drew prominent attention to the danger of anthrax to the workers from this material. In his report Dr. Russell cites numerous published reports in France, in one case dating as far back as 1777, in which workmen had been attacked with charbon and boils in opening and sorting bales imported from Russia. In France and Germany, indeed, use of this material appears to have contributed by far the largest share of cases of anthrax. The outbreak in Glasgow in 1879 was due to virulent infection from Russian horsehair. Nine persons were attacked, of whom seven died. Seven of the cases were of the internal type. In 1893 Chauveau[29] described a small outbreak from horsehair in a village in France which has many points of resemblance to that described by Dr. Russell. In less than four months there were seven cases with six deaths. Two of the cases were of the gastro-intestinal type and two of malignant anthrax œdema without external development of a malignant pustule. In this case China horsehair was believed to have been the cause. Since 1878 no case of anthrax was known to have occurred in Glasgow until an outbreak of five cases in 1900. During this second outbreak the particular factory in which all the early cases had occurred escaped, the firm having since 1878 discarded the use of Siberian hair altogether.

The possibility of steam disinfection suggests itself as the only effective means of removing the danger from manipulation of dangerous wool and horsehair. In the case of wool no thorough and minute inquiry as to whether this method is practicable has ever been undertaken. In 1880 a manufacturer in Bradford for the space of 12 months placed all bales of alpaca and mohair in a steaming apparatus at a pressure of five pounds for 12 hours. No experiments were made to see how far sterilisation was accomplished. The firm did not find that the material was injured for spinning purposes. Subsequently the firm discontinued the use of Van mohair wool and the need for steaming disappeared. To obtain certain effects, such as the fixing of a dye material on the wool, mohair after it has been carded is still exposed for one and a half hours to steam at five pounds pressure without injury. When high pressures, such as are commonly employed in disinfecting machines in this country, are used, with the increased temperature, there is increased tendency to damage the material. Thus Dr. W. A. Evans,[30] medical officer of health of Bradford, has on several occasions tried to disinfect dangerous wools by means of a Washington Lyons apparatus and says:—"Although my disinfection may have been successful the wool has almost always been irretrievably ruined, altered in texture and very much in appearance."

The practicability of steam disinfection of horsehair has been thoroughly tested in this country and in Germany. The problem of steam disinfection when applied to horsehair and bristles is presented perhaps in its most difficult form. The natural resistance of the spores is increased by the dirt and grease of the material in which they are imbedded. The hair is tied tightly together and in the case of mane hair or combings the bales weighing about five hundredweights are hydraulically press-packed. Recent experiments by Proskauer and Elsner[31] have shown, too, that anthrax spores artificially placed on horsehair are killed with greater difficulty than when on silk. The experiments in this country by Webb and Duncan[32] have been carried out with known infected material, that is with horsehair in its natural condition in which the presence of anthrax had been demonstrated. The experiments were made in a Washington Lyons apparatus. They found that dust shaken from China hair subjected to a temperature of about 245° F. for 20 minutes appeared sterilised. When, however, the horsehair thus treated had been subjected to the process of carding and one horsehair fibre separated from another the anthrax bacillus was cultivated from the dust so produced. From this the conclusion was drawn that the process of carding liberated the spores which had escaped the first disinfection owing to its environment of grease and dirt. Nevertheless, numerous experiments with dust from combing machines showed that the disinfecting process had killed the great bulk of the bacilli and lowered the vitality of those which had survived. They could not sterilise horsehair in bulk by exposure to steam at about 24 pounds gauge pressure (253° F. actual temperature), even for 45 minutes. When the results of the German experiments became known Mr. Webb reduced the pressure at which he worked and found that equally satisfactory results were obtained with temperatures of 226° and 230° F.

The German experiments conducted in the Imperial Health Office extended from 1894 to 1900.[33] They have been very thorough owing to statements made by manufacturers that the hair made to undergo the preliminary steam disinfection was reduced in quality and, therefore, a source of loss. In the German experiments reliance is based on current saturated steam and not on superheated steam. Anthrax spores are killed by exposure to current saturated steam at 100° C. in five minutes, whereas 20 minutes' exposure is required when superheated steam at from

[33] [illegible] dheitsamte, vol. xv., pp. [illegible]

110° to 120° C. is used. With use of superheated steam spores in the centre of objects to be disinfected may be killed, while those lying on the surface and directly exposed survive. The temperature recorded in these experiments in the centre has been from 99° to 101° C. and in the latter from 105° to 141° C. The only explanation is that the superheated steam as it penetrates into the object gives up its latent heat and acts on the spores in the form of saturated steam.

Leaving out of consideration hair white or light grey in colour, which would be turned yellow, the general conclusion arrived at by the experimenters is that provided the pressure does not exceed two and a quarter pounds, equivalent to a temperature of 219° F., and due precaution is exercised in the management and regulation of the apparatus during the time of disinfection, no injurious effect is produced in the hair which could be considered as diminishing its value or causing it to be a source of loss. Success, however, is only to be attained by minute care in detail: (1) in the construction of the apparatus designed so as to allow the steam to enter from above and to find its exit at the lower part of the apparatus; (2) provision of pressure gauges marking clearly the point when the pressure of two and a quarter pounds has been reached and the provision of thermometers to control the temperature indicated by the pressure gauge; and (3) constant attention to the apparatus during the time disinfection is in progress.

Frequent occurrence of cutaneous anthrax among brushworkers in Belgium has recently caused inquiry to be made there also as to the possibility of removing danger in manipulation of the material. Satisfied of the impracticability of making steam disinfection obligatory in the numerous small workshops throughout the country (a feature of the industry everywhere which adds to the difficulty of controlling the danger) Dr. Glibert, principal medical inspector, has directed his attention mainly to experiments to determine how far simple boiling might be regarded as efficient. Using spores of anthrax which resisted a 5 per cent. solution of carbolic acid for one month, in none of his experiments could he find them capable of developing even after only 15 minutes' exposure. At the same time special precautions must be taken to secure penetration of the heat throughout the material because a thermometer placed in the centre of a closely tied bundle of horsehair 15 centimetres in diameter never registered 100°C., although the liquid in which it was immersed was maintained constantly at this temperature for one and a half hours. These experiments seemed to him the more satisfactory as they followed on unsuccessful results with similar resistant anthrax spores subjected by him (under rigorous conditions) to the accepted procedure of steam disinfection in one of the best equipped continental factories.

To secure certain destruction of all anthrax spores in horsehair absolute reliance cannot be placed on either steam disinfection or simple boiling. Adoption of one or the other is a very material safeguard and steam disinfection is practicable for all kinds of hair except that which is of white colour provided due care is observed. Risk, however, must always be run by those persons who prepare the hair for disinfection.

SOCIETY OF APOTHECARIES OF LONDON.—At a meeting of the Court of Assistants held on March 21st the following resolutions were adopted:—

1. That steps be taken to urge upon the Government the desirability of the amendment of the Midwives Act, 1902, in the following respects. (a) by a provision for payment by the local authority of members of the medical profession called in by midwives in cases of danger or difficulty as defined by the rules framed by the Central Midwives Board; (b) by provision for payment to the members of the Board of their reasonable travelling expenses and other disbursements incurred in connexion with their duties.

2. That a copy of the above resolution be sent to His Majesty's Privy Council.

A vote of thanks was passed to Mr. E. Parker Young for his services as the representative of the society upon the Central Midwives Board during the last two years. Mr. Parker Young, in acknowledging the vote, explained that during his term of office he had been present at every meeting of the Board and had signed nearly 10,000 midwives' certificates. Subsequently Mr. Parker Young was re-elected as representative for another year. The report of the adjudicators for the Gillson scholarship in pathology of the annual value of £90 was considered and adopted, the successful candidate being Mr. E. W. A. Walker, M.A., M.D. Oxon

The Hunterian Lectures

ON

THE PHYSIOLOGY AND TREATMENT OF SURGICAL SHOCK AND COLLAPSE.

Delivered before the Royal College of Surgeons of England on March 6th, 8th, and 10th, 1905,

BY J. P. LOCKHART MUMMERY, M.B.,
B.C. CANTAB., F.R.C.S. ENG.,

HUNTERIAN PROFESSOR OF SURGERY, ROYAL COLLEGE OF SURGEONS OF ENGLAND; HONORARY SURGEON TO KING EDWARD VII.'S HOSPITAL, ETC.

LECTURE III.[1]

Delivered on March 10th.

TREATMENT AND PREVENTION.

The introduction of fluids into the circulation.—The first attempt at this method of treating shock or collapse was by transfusing the blood from the veins of a healthy person to the veins of one dying from loss of blood. Transfusion and intravenous infusion were not only used more than two centuries ago for the treatment of shock and collapse but were much vaunted as a means of curing disease and of indefinitely prolonging life in the aged, and the method was so much abused in Paris in the early part of the eighteenth century that the Government passed laws to stop the practice and imposed serious penalties for those caught performing it. The value of intravenous infusion in the treatment of shock was drawn attention to in 1893 by Mr. Mayo Robson in a paper read before the Clinical Society. Transfusion is now never practised but curiously enough the name still persists and is commonly incorrectly used to describe the intravenous injection of water or salt solution.

There are four principal ways in which fluids may be introduced into the circulation for the treatment of shock: (1) By intravenous infusion; (2) by intra-abdominal infusion; (3) by rectal injection; and (4) by subcutaneous injection.

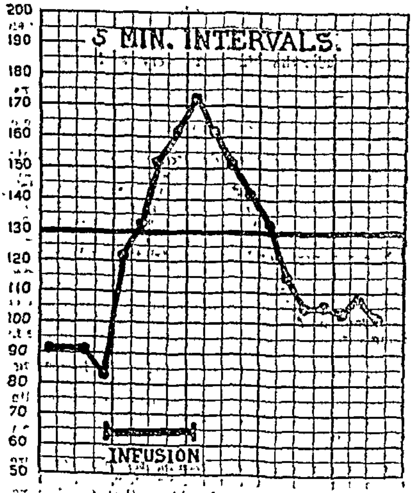
Very opposite views have been held by different surgeons as to the advantages or otherwise of intravenous infusion in the treatment of shock. The arguments for and against it have been often founded upon purely hypothetical reasoning or upon isolated observations. With the experimental data now available and observations made of the changes in blood pressure with a sphygmometer of the results of this method it is now, I think, possible to arrive at definite conclusions with regard to it. Intravenous infusion raises the blood pressure in all conditions of shock; this has been proved by experiment upon animals by Crile and by observation on patients by myself and others. The rise in blood pressure occurs immediately and gradually increases with the continuance of the infusion. In cases of moderate shock where the vaso-motor centres are still active the pressure is well sustained after infusion, but in profound shock the pressure falls again after a short time unless the infusion is continued. Saline infusion acts by increasing the circulating fluid in the circulation and thereby indirectly raising the blood pressure. Its value is limited in the treatment of shock by the fact that it does not combat the cause of the fall in blood pressure which is the loss of peripheral resistance in the circulation. It is obvious that saline infusion does not act by controlling the capacity of the circulatory system but by diminishing the disproportion between the quantity of circulating fluid and the capacity of the circulatory system.

When salt solution is introduced into the veins in large quantities it begins after a time to escape from the blood-vessels into the tissues and produces œdema. Sherrington, and Cobbett and Roy have demonstrated that in shock a transudation of the fluid elements of the blood takes place through the walls of the blood-vessels into the tissues and that the specific gravity of the tissues is found after shock has persisted for a short time to have decreased owing to the [illegible] om the bloo[illegible] om the bloo[illegible] of the fluid from the circulation after intravenous infusion. This escape of the fluid from the circulation becomes after a time so rapid that if saline infusion is continued the blood pressure is not even sustained but falls while the solution is being run into the veins. A case is reported by *Archard* and Paisseau of a woman who, suffering from severe shock and collapse after an abdominal operation, was treated by continuous subcutaneous saline injection, ten litres of fluid being introduced in this way in 24 hours. She died from pulmonary œdema, and general œdema of the tissues was found post mortem. Crile has demonstrated that after about 320 cubic centimetres of fluid per kilo of body weight have been injected the fluid escapes into the tissues and causes œdema. So far, therefore, as *raising the blood* pressure is concerned the value of saline infusion is limited in the treatment of shock. It is nevertheless one of the most effective means that we *possess* of raising the blood pressure.

---

[1] Lectures I. and II. were published in THE LANCET of March 18th (p. 696) and 25th (p. 776), 1905, respectively.

FIG. 12.



The result on the *blood pressure* of a patient suffering from severe shock of an intravenous infusion of salt solution. Four pints were infused.

In a case of dangerous and subsequently fatal shock in which I had the opportunity of observing the *blood pressure* by means of the sphygmometer during intravenous infusion, I observed a rise in the blood *pressure from* 85 *millimetres* of mercury to 170 millimetres in the space of a little over 20 minutes as the result of the introduction of four pints of saline solution into the *veins* of the arm. This is a tremendous rise in blood *pressure*. The *pressure* in this case began to fall again at once and fell slowly until it reached a point just above the original level in one and a quarter hours (see Fig. 12). There is another way in which [illegible] saline infusion is of value in the treatment of shock besides [illegible] already been stated, [illegible] inspissated and its [illegible] ndoubtedly a factor of very considerable importance in producing a fatal issue from shock, as the blood may become so thick that it will not pass through the smaller vessels and capillaries. Watson Cheyne has noted that coagulation of the blood in the pulmonary vessels may occur and materially increase the probability of a fatal issue. Cobbett and Roy have recorded that in dogs in which shock had been artificially produced the blood eventually became so thickened that it would only flow with difficulty from the largest arteries. This being the case it is obvious that saline infusion is of considerable value in counteracting this tendency for the blood to become thickened, and that far from saline infusion causing a dangerous [illegible] he blood, as *has been su*[illegible] capable of reducing t[illegible] Quite apart, therefore, from its value in raising the blood pressure saline in[illegible] to reduce the specific gravity o[illegible]

[illegible] performing infusion. The one most commonly described is that of exposing the vein (usually the median basilic), ligaturing it below, incising it, and tying a glass cannula into the upper end; the fluid is then allowed to flow into the vein from a glass funnel attached to the cannula by an indiarubber tube. A quicker and, I think, a better method is to use a sharp metal cannula and to push it through the skin and vein wall in a direction towards the heart; with a little dexterity this is very easily done and the metal cannula can be got into a much smaller vein than the glass one. In treating shock the results are much better if the patient is infused early instead of waiting to infuse until the patient has reached a dangerous degree of shock. And it is much better to infuse moderate quantities of fluid of about a pint at a time repeated at intervals as the patient's condition seems to require it than to infuse a large quantity at one time. The cannula can be left in the vein and the tube wrapped round the arm ready to reinfuse when necessary. It is very useful to have a blood-pressure record kept with a sphygmometer (which can easily be done by the nurse) and, to be guided as to the amount of fluid and the times at which to infuse by the record of the actual pressure. This is far better than the haphazard method of infusing only when the patient's condition is dangerous. The best temperature for the fluid is about 3° above normal body temperature to allow for [illegible] bing.

[illegible] intravenous infusion is [illegible] drachms of common s[illegible] ieously called normal salt solution on the supposition that it represents a close approximation to normal blood serum in composition. This is, however, not the case; common salt often contains several extraneous chemical substances and even if pure salt is used the solution differs considerably from blood serum. Several forms of physiological salt solution have now been intro- [illegible] which when dissolved in a pint of water give a physiological solution. Halsted's solution which has been used for a long time in his clinic consists of NaCl, 0·9; potassii chloras, 0·03; calcii chloridum, 0·01; and water, 100. In an emergency the solution made up with common salt is very useful and can be used safely. But I believe that many of the symptoms, such as rigors and sweating, which are occasionally seen after intravenous infusion with a solution of common salt are due to the chemical composition [illegible] and that it results from excessive dilution of the blood in the lungs. I have never seen this complication though I have seen and done this procedure a great many times. I should very much doubt its being due to the cause stated as it is hardly conceivable that the blood in the lungs can be diluted to any appreciable extent.

As I have already mentioned, there is no object in infusing very large quantities of fluid as after a time the fluid merely escapes into the tissues and produces œdema. The best guide to the amount of fluid which should be infused is the blood pressure which should for this purpose be measured with a sphygmometer. The rate at which the fluid is allowed to flow into the veins appears to be of considerable importance. A too rapid flow is liable to cause unpleasant symptoms. Thus it has been shown by experiment that a rate of flow exceeding three cubic centimetres per minute in a rabbit produces serious symptoms and Bolognesi has said that though there is no toxic dose of artificial serum there is a definite toxic rate of injection.

In collapse following a severe hæmorrhage where the fall [illegible] exhaustion of the vaso-motor [illegible] circulation resulting from a [illegible] circulating fluid, intravenous [illegible] ition is by far the best and most efficacious remedy. It directly treats the cause of the condition since it supplies fresh fluid to the circulation in the place of that lost. It is true that though we can in this way replace the amount of fluid lost and so re-establish the pressure, we do not replace the corpuscles and so leave the blood much thinner in many of its essential elements. In practice, however, this is of comparatively little consequence. It has been proved that serum alone and even physiological salt solution is capable of taking up oxygen in the lungs and of giving it off to the tissues, so that the circulation can be maintained, even though half the blood in the body has been replaced by physiological salt solution, at any rate in animals. Zachrisson has demonstrated that an animal can be restored to life by saline infusion after a quantity of blood not exceeding 3 per cent. of its body weight had been removed.

As I have already shown, in shock the rise of blood pressure following saline infusion is not sustained but the blood pressure soon falls again to its former level. In the collapse following hæmorrhage, on the other hand, the rise in blood pressure resulting from saline infusion is sustained. The value of saline infusion in the treatment of collapse following extra-vascular hæmorrhage is supported by abundant clinical proof. On one occasion I had an exceptional opportunity of testing its value in collapse of this nature. The patient was a man of about 30 years of age who was operated upon for Jacksonian epilepsy. A large portion of his skull was removed for the purpose of exposing the Rolandic area of the cortex. Before the dura mater had been opened, however, furious venous hæmorrhage occurred from the diploic veins. For some time all attempts to control the hæmorrhage were unavailing and it was not stopped until a very large quantity of blood had been lost and the patient had been reduced to an almost moribund condition. He was quite pulseless, stimulants had no effect, he was quite unconscious, and death seemed imminent. Nearly four pints of saline solution were infused into his veins with the result that he immediately regained consciousness and his circulation was re-established. His blood pressure did not again fall and he completely recovered and beyond a certain amount of anæmia which persisted for a week or two his circulation was entirely restored.

In cases of collapse due to sudden inhibition of the functions of the vaso-motor centres such as follows blows upon the genital organs or in the splanchnic area or any other violent afferent nerve stimulus, saline infusion is often effective, though not to so marked an extent. Here it is the loss of peripheral resistance that is the cause of the condition and saline infusion can only affect this indirectly.

The treatment of shock by intra-abdominal infusion of salt solution.—The method of treating shock occurring during an abdominal operation by the introduction of large quantities of water or saline solution into the peritoneal cavity has long been practised by many surgeons. It was first described in a paper by Lawson Tait in 1887, though Keith and others had undoubtedly practised it many years before this. When we remember the great surface area of the peritoneum and its great power of absorption it is at once obvious that it is a most effective method of introducing water into the circulation.

A great deal can be done to ward off shock or to treat it if present by frequently irrigating the peritoneum during an abdominal operation; or even by simply filling the abdominal cavity with water or, better still, saline solution just before closing the abdominal wound. It raises the blood pressure in exactly the same way as does intravenous infusion. The best solution is a sterile physiological salt solution at a temperature of from 104° to 108° F. There has been a considerable amount of discussion as to whether it is justifiable to use this method in cases where septic peritonitis or other septic conditions are present. Greig Smith advocated it in all septic conditions; the majority of surgeons, however, have condemned it in septic cases on the grounds that it diffuses the septic material and results in infection of a wider area. This view seems at first to be correct but recent researches have shown many reasons why this view is not tenable. Thus Clark and Norris have proved that flushing the peritoneum with saline solution causes a marked increase in leucocytosis, both during and after the operation. They carried out a series of experiments to test whether the introduction of saline solution into the abdominal cavity increases the danger of septic infection or otherwise. These results show that far from increasing the dangers of infection it minimises them. They injected animals intra-abdominally with one cubic centimetre of a bouillon culture of a streptococcus and 100 cubic centimetres of saline solution. Control animals were injected similarly with one cubic centimetre of the bouillon culture only. All the control animals died, the average length of life being 13 hours. Of the experimental animals 44 per cent. lived and of those that died the average life was 88 hours. This certainly proves that dilution of the septic material greatly minimises its power of damage to the peritoneum. Salieri in 1902 proved that the resisting power of the peritoneum could be increased by injection of normal salt solution. More recently Mikulicz and Miyoke have proved that the resisting powers of the peritoneum can be greatly increased by the production of leucocytosis. Mikulicz in his Cavendish lecture states that the intraperitoneal injection of normal saline solution gives rise to a marked hyperleucocytosis in the peritoneal transudate. There can, I think, therefore be little doubt that intra-abdominal infusion is not only safe but advantageous, apart from its action upon the circulation in abdominal operations where septic processes are present. As shock is perhaps most often seen in abdominal operations performed for conditions where sepsis is present I believe this to be a point of no little importance in the treatment of shock by this method.

Rectal infusion of saline enemata.—Rectal enemata of saline solution have a more limited range of usefulness than intravenous infusion. In cases of severe shock where the circulation has almost failed the fluid is not absorbed into the circulation fast enough to be of service, as there is not sufficient circulation to carry it into the great vessels. It is, however, a very useful method in the early stages of shock and as a preventive method.

Subcutaneous infusion.—This method is much more popular on the continent than it is in this country. It has no advantage over intravenous or rectal infusion and has additional disadvantages. Enough fluid to be of any practical utility can seldom be introduced rapidly and unless the circulation is fairly efficient the solution is only very slowly absorbed or not at all. And in addition the injection of so much fluid under the skin is often very painful.

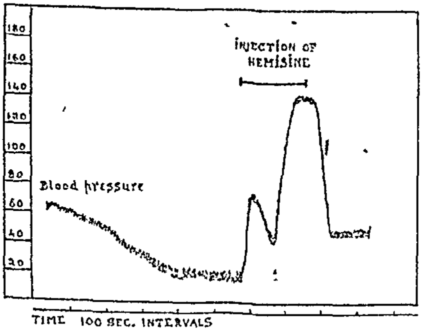
The treatment of shock by raising the peripheral resistance with drugs.—The morbid physiology of shock teaches us that the essential factor in the production of the great fall in blood pressure which occurs in shock, and which is the cause of the condition, is the loss of peripheral resistance in the circulation and that this is due to a general vaso-dilatation from loss of control by the vaso-motor centres. It is at once obvious that if we can find a means of causing constriction of the peripheral vessel and so raising the blood pressure independently of the vaso-motor centres we shall have an effective means of treating shock. There are several drugs which cause peripheral vaso-constriction and so raise the blood pressure independently of the vaso-motor centres. The most important of these are suprarenal extract and its derivatives, especially adrenalin and hemisine, and ergot. These drugs act directly upon the walls of the blood-vessels, causing vaso-constriction, and a very considerable rise in the blood pressure follows their administration. These drugs, in fact, afford us a means of artificially increasing the peripheral resistance to an almost unlimited extent whatever be the condition of the vaso-motor centres. Adrenalin will raise the blood pressure in all conditions of shock when the vaso-motor centres are completely exhausted and even when they are destroyed.

The action of adrenalin in raising the blood pressure was first demonstrated by Oliver and Schaffer. They showed by experiments upon dogs and rabbits that the intravenous injection of adrenalin is followed by a very great rise in the blood pressure, this rise occurring after a latent period of about 20 seconds. The rise in the blood pressure was not sustained for more than a few minutes. If, however, the weak solution of the extract was allowed to flow into a vein the blood pressure rose and remained at a high level for as long as the flow was continued. Gattliel confirmed these experiments upon rabbits and further showed that intravenous injection of the extract of suprarenal gland would raise the pressure considerably above the normal in animals in which the blood pressure had been artificially reduced previously to the injection and that in these circumstances the pressure was sustained for a longer period than in the normal animal. Muhlberg and Miles injected adrenalin intravenously into rabbits whose blood pressure had been greatly reduced from vaso-motor exhaustion following the administration of ether. They found that a very great rise in blood pressure followed the injection which persisted for a few minutes, the blood pressure then falling again to the original level.

Crile has confirmed these experiments upon dogs and has shown that adrenalin is able to raise the blood pressure under all conditions. It raises the blood pressure in profound shock just as easily as in the normal animal. If the medulla and the spinal cord of an animal are cocainised, adrenalin will still raise the blood pressure. When the splanchnic nerves are divided or the cord is divided, or even when the medulla is destroyed, this rise in blood pressure still takes place. An animal that had been apparently dead for 15 minutes from the discharge of an electric current was resuscitated by the intravenous injection of adrenalin, combined with rhythmic pressure upon the heart and artificial respiration. In one experiment Crile kept a decapitated dog alive by intravenous infusion with adrenalin and artificial respiration—that is, the animal was alive in the sense that its heart continued to beat during that period. These experiments show that the action of adrenalin in raising the blood pressure is quite independent of the vaso-motor centres in the medulla.

Unfortunately, adrenalin is very rapidly oxidised by the tissues and its effects are fleeting. Injected intravenously its effects last from two to five minutes so that to be used effectively for raising the blood pressure it is necessary *to administer it by continuous intravenous infusion.* Administered in this way the blood pressure can be maintained for a very considerable time at almost any desired height when the vaso-motor centres are completely exhausted or even destroyed. It is in many ways *unfortunate that adrenalin has to be administered* continuously in order to obtain the best results. Hemisine is a similar drug to adrenalin and is in some ways more convenient as it is put up in tabloid form. I have tried administering hemisine in various ways to see if its action could be prolonged. I have tried giving it per rectum, by the mouth, and subcutaneously; except intravenously administered, however, it has but little effect upon the blood pressure. This is probably due to its local action upon the blood-vessels preventing it from being absorbed into the circulation. Injected intravenously in weak solutions in the human subject it causes a great rise in the blood pressure (see Fig. 13). A weak solution poured into the peritoneal cavity during an abdominal operation upon a child at a stage when the child was suffering from a considerable amount of shock caused a rapid rise in the blood pressure and allowed the operation to be finished and the child to be got back to bed without any further signs of dangerous shock developing (see Fig. 14). Crile records the case of a patient dying from shock who was kept alive for eight hours by the administration of adrenalin.

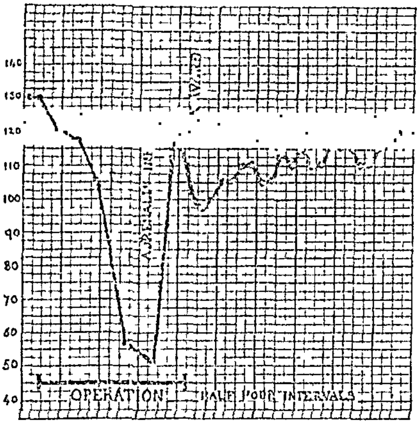
FIG. 13.



The effect of hemisine in raising the blood pressure in shock.

Craig of Columbia reports two cases of surgical shock treated by intravenous saline infusion with extract of suprarenal gland. The first case was one of compound fracture of the elbow caused by a gunshot accident. The patient was pulseless, cold, and suffering from a severe degree of shock. Saline infusion with a solution containing the extract caused a very favourable reaction. The second case was one of a severe compound fracture of the skull. This was treated in the same way and with equally good results. I know of a number of instances in which cases of surgical shock have been treated by slow intravenous infusion with adrenalin solution and the results have been most satisfactory so long as the infusion was continued but in several of the cases the condition relapsed so soon as the infusion was stopped. In no case that has come within my knowledge has any unpleasant symptom developed as the result of the infusion.

FIG. 14.

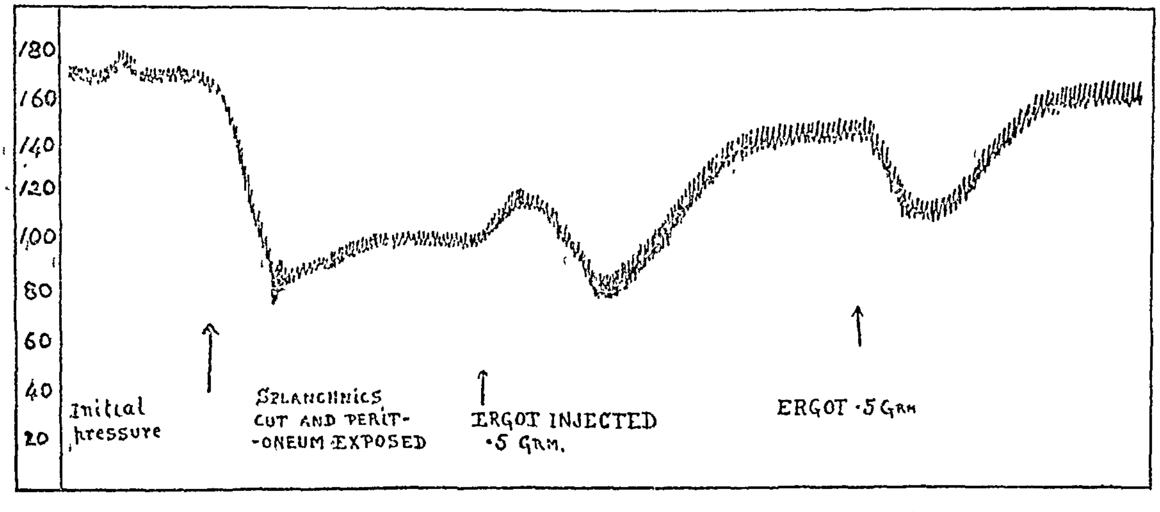


Blood pressure chart. A severe abdominal operation on a child during which shock developed. A 1 in 20,000 solution of adrenalin was poured into the abdominal cavity. The patient recovered.

The number of cases in which adrenalin has been used clinically in the treatment of shock are as yet few but I think there can be no doubt that it affords a very valuable means of treating this condition. It gives us absolute control over the blood pressure and enables us to maintain it at or above the normal level for a considerable number of hours when a patient is suffering from profound shock. I believe it affords us a certain means of preventing a patient from dying on the operating table and that it will prove in the future to be the means of saving life in many cases of post-operative shock. When administered intravenously it should be used in very weak solutions. Crile advises that a solution of from 1 in 50,000 to 1 in 100,000 should be used. I have used it in a solution of 1 in 20,000. At first, at any rate, it is not advisable to use stronger solutions. The solution should be allowed to flow into the vein in the same way as in performing intravenous saline infusion. It should, however, only be allowed to flow in quite slowly and its effects should be watched. The best way, of course, is to take repeated measurements of the blood pressure with a trustworthy sphygmometer and to endeavour to keep the blood pressure at about the normal level by varying the flow of the solution as the height of the blood pressure indicates. A very good rough guide, however, to the amount that should be used and the rate of flow may be obtained by feeling the pulse. In cases of abdominal section it can be conveniently used by putting some of the same solution into the abdominal cavity. I have had a special infusion apparatus made for the administration of adrenalin in cases of shock. This apparatus has a reservoir graduated in centimetres and the rubber tubing is closed by a screw-cock; this allows the solution to be infused five cubic centimetres at a time or at the rate of as many cubic centimetres per minute as is found to produce the best results. If strong solutions are used it causes spasm of the heart from direct action upon the heart muscle. Zaneway records a case where 20 minims of a 1 in 1000 solution were injected intravenously. After an interval of nearly five minutes the blood pressure rose to a great height, reaching 230 millimetres of mercury in the course of the next three minutes. This was followed by a rapid fall, the pulse stopped, there were collapse, vomiting, and delirium, and recovery was not complete for some hours; very serious symptoms in fact resulted, but the dose was most excessive and the fact that death did not result from such a dose shows that the weaker solutions can be used safely. Von Fürth has pointed out that the great rise of blood pressure accompanying its administration might cause apoplexy in persons predisposed to that condition. If used in sufficiently dilute solutions, however, this danger should not arise.

The most serious objection to the use of adrenalin or hemisine in the treatment of shock is that they have to be administered continuously and I have tried to find some other drug which, while acting in the same way, produces a more prolonged result. I have tried various drugs and the one which has given the best results and which seems to solve the difficulty is ergot. By the kindness of Dr. A. Waller, the director of physiology of the University of London, and by the help of Mr. W. L. Symes, who kindly performed the experiments for me, I have been able to test the value of ergot in the treatment of shock upon animals. The experiments were done upon cats. The blood pressure was reduced to the level of shock by division of the splanchnic nerves and exposure of the intestines or by pithing the animal, or by both methods (see Fig. 15). When the blood pressure had been reduced to the level of profound shock, half a gramme of ergot dissolved in five cubic centimetres of salt solution was injected into the jugular vein. The first effect was an immediate slight fall in the blood pressure. This was probably due partly to the cold solution; the pressure then rose slowly and steadily and in about eight or ten minutes had reached a level above the initial pressure. This rise in the pressure was maintained for a considerable time, certainly as long as 20 minutes in some of the experiments. If, when the pressure had reached the high level a second injection was given it again rose to a still higher level. In the pithed animal, whose pressure had fallen almost to the abscissa line and whose respiration had stopped, artificial respiration was supplied and ergot was injected; the blood pressure then rose to over 150 millimetres of mercury and remained at this level for a considerable time (over 20 minutes).

FIG. 15.



The result of the injection of ergot upon the blood pressure of an animal previously reduced to shock by division of the splanchnics and exposure of the peritoneum. After a preliminary fall the pressure rose, and after the second injection reached a point equal to the initial pressure where it remained for over 20 minutes.

Unfortunately, ergot is a very uncertain drug and attempts to separate its active principles have hitherto been failures. Thus different samples of ergot may act quite differently owing to the fact that they contain more or less of one or other of the active principles. It is to be hoped that in time some one will succeed in separating the blood pressure raising principle of ergot from its other constituents. The preparation of the drug which I have used in most of the experiments is Parke, Davis and Co.'s aseptic ergot. This preparation has the advantage of being sterilised so that it can safely be injected into the veins and its blood pressure raising properties seem to be very fairly constant. The solution used consisted of two grammes of ergot diluted with 20 cubic centimetres of normal salt solution of which from five to ten cubic centimetres were injected at a time. The blood pressure commenced to rise in from 40 to 80 seconds after the injection, the pressure then rose slowly and steadily, the maximum pressure often not being reached for ten minutes or more. The pressure was well sustained at the high level for a considerable time. The injection did not cause any bad effect upon the heart. After a time the heart was slowed but the beats were increased in force and length. Marked and continuous contraction of the circular muscle fibres of the intestine could be seen after the injections. These experiments were repeated upon dogs but without result. Ergot appears to be quite inactive in dogs as no result whatever followed its injection even when very large doses were used. There is very good reason to suppose, however, that the results which follow the injection of ergot in human beings are similar to those which follow its injection in cats. It was found in the experiments that the ergot could not always be depended upon. Thus on one occasion an injection of ergot would be followed by a well-marked rise in the blood pressure, while on another occasion an exactly similar dose would produce no effect whatever. I believe this to have been due to variations in the drug, though an apparently identical preparation was used. Some other preparations of ergot which were tried proved quite useless.

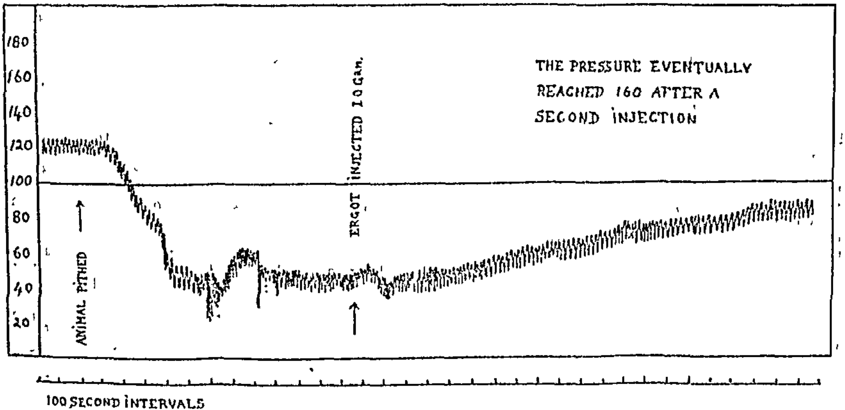
I think these experiments show that ergot raises the blood pressure by direct action upon the peripheral blood-vessels quite independently of the vaso-motor centres and that the blood pressure can in this way be raised to the normal level again when it has fallen as the result of exhaustion or even destruction of these centres. That the injection of ergot is a valuable means of treating shock is, I think, clearly proved. In an animal whose brain had been destroyed by pithing and whose blood pressure had fallen from 120 millimetres of mercury to between 40 and 50 millimetres of mercury the blood pressure was not only restored to the normal level again by the injection of ergot but was raised to between 150 and 160 millimetres of mercury and kept at about that level until the animal was killed at the end of the experiment (see Fig. 16). In one of the experiments in which the animal had been reduced to a condition of profound shock by destruction of the medulla and division of the splanchnics and whose vaso-motor centres were inactive (proved by the fact that electrical stimulation of the sciatic nerve caused no rise in the blood pressure) the injection of ergot was not followed by any rise in the pressure and, the pressure falling, hemisine was injected but without result and the heart failed entirely. The heart failure was found to have been due to a block in the tracheal cannula interfering with respiration. After the heart had stopped beating for six minutes it was made to beat again by rhythmic pressure and the injection of hemisine solution and the blood pressure rose to 190. The hemisine injection was then discontinued. The blood pressure, however, instead of falling again, remained above 90 for over 30 minutes as the result of the ergot which had previously been injected. If ergot is injected hypodermically it acts similarly but not so rapidly.

Jacobi has investigated the action of a derivative of ergot which he calls sphacelotoxin. This substance when injected into an animal causes a great rise in the blood pressure from *its action upon the walls of the blood-vessels, since Jacobi* has demonstrated that it raises the blood pressure after division of the spinal cord. The great advantage of ergot over adrenalin is that its action is more prolonged and that one dose is sufficient to keep up the blood pressure for some time and also that it can be used hypodermically and has not necessarily to be infused intravenously. Ergotin I have also tried but though it raises the blood pressure it only does so for about five or ten seconds and is therefore quite useless. Hazeline, which is a useful local styptic, does not seem to have any effect upon the blood pressure when injected intravenously. Piperidine and its alkaloid coniine cause when injected a very great increase in the blood pressure owing to their action upon the peripheral vessels but, like adrenalin, their effect is transient and, moreover, their prolonged administration causes paralysis. Nicotine injected intravenously causes a tremendous increase in the blood pressure and its action is peripheral since the effect is produced even after removal of the spinal cord. Its effects are transient, however, the blood pressure falling to, or even below, the normal again in a few minutes.

It has recently been discovered that the extract of the infundibular portion of the pituitary gland causes, when injected intravenously, constriction of the peripheral arterioles and a consequent rise in the blood pressure similar to that obtained by the administration of adrenalin. [illegible] is a great advantage.

In using any of these drugs for the treatment of severe [illegible] on, however, as the pressure has [illegible] ministered in very small doses as [illegible] into the peripheral circulation. It is not possible for a single observer thoroughly to test the value of a new method of treatment for such a condition as shock. Shock is a condition which one does not wish to find and which one takes means to avoid and it is not easy to find bad cases of shock which can be treated by new methods. Cases of shock usually occur unexpectedly and often at most inconvenient times, when it is impossible for the surgeon to watch them himself. It is only by the accumulated experience of many surgeons that such methods of treating shock can be placed upon a sound basis of practical experience.

FIG. 16.



The effect produced upon the blood pressure by an injection of ergot in an animal reduced to a condition of profound shock by destruction of the brain and medulla.

THE PREVENTION OF SHOCK.

As is the case with sepsis, so also with shock, it is in the prevention of this condition rather than in its treatment that we shall be successful. Shock is much more easily prevented than it is treated once well established. It has been supposed that shock can be prevented by the administration of strychnine during the operation but, as I have already shown, this is not only erroneous but absolutely harmful, as of itself it tends to produce or, at any rate, to increase shock. Brandy and other stimulants are also and for the same reason equally useless. It is a well-known fact, however, that while a single continuous exertion or stimulus causes exhaustion, an intermittent exertion or stimulus causes hypertrophy and increases the resistance to exhaustion. Now though we know that the administration of strychnine in large doses will cause exhaustion of the vaso-motor centres and so produce shock, it seems also probable—nay, almost certain—that the intermittent administration of small doses of strychnine at reasonable intervals should cause hypertrophy and increase the tone of the vaso-motor mechanism, together with all the other nerve centres. We assume this to be true in fact, or why is strychnine used as a tonic? I think that strychnine may be made use of to prevent shock in this way if it can be administered in small doses at reasonable intervals, for, say, a week or ten days previously to an operation, following which shock is feared.

Improving the general tone of the patient's nervous system by a change of air, &c., previously to a serious operation are [illegible] methods of preventing shock and are [illegible] can be done [illegible] an operation which tend to lower the blood pressure and so to increase or to cause shock and by avoiding or modifying these procedures. One of the most important factors is the anæsthetic. An anæsthetic undoubtedly does much to prevent the occurrence of shock in severe surgical procedures by blocking or minimising the effect of afferent impulses to the central nervous system. It is difficult to prove this as no operation which could possibly result in shock is ever now performed without an anæsthetic (local anæsthesia of course acts in the same way). But before the introduction of anæsthetics shock was much more often seen and was more severe, if one can judge by the results of the operations of those days; though the speed at which they were necessarily done did much, no doubt, to diminish subsequent shock. It is, however, I think, proved conclusively by the fact that severe shock often results from mutilation caused by accidents that would not result, or not to the same extent, if a similar or even more severe mutilation were caused during an operation under anæsthesia. There cannot, I think, be any doubt that other things being equal operations performed under ether anæsthesia are less liable to be followed by shock than those performed under chloroform anæsthesia.

An argument that is sometimes used in favour of chloroform anæsthesia in contradistinction to ether is that hæmorrhage is less profuse and not so likely to be troublesome. The reason for this is, of course, that chloroform causes lowering of the blood pressure while ether tends to raise it. The hæmorrhage can, however, be prevented by careful operating and by the use of local hæmostatics and the prevention of shock is of much greater importance as a rule than the prevention of hæmorrhage. Anyone who takes the trouble of keeping a chart of the blood pressure every few minutes during severe operations will very soon become convinced of the great disadvantages of chloroform as an anæsthetic in these cases. In all severe operations and surgical procedures which are liable to be complicated by shock ether or the C.E. mixture should be used for the production of anæsthesia.

There are certain procedures during an operation which are peculiarly liable to be followed by a sudden fall in blood pressure and these should be avoided. For instance, evisceration. Turning the intestines out of the abdomen during the performance of laparotomy is invariably followed by a sudden and dangerous fall in the blood pressure. This is probably largely mechanical in its action, as it allows of large quantities of blood to collect in the splanchnic area. It is certainly a procedure carefully to be avoided if possible. There can be no possible doubt that the length of the operation is a most important factor in the causation of shock and that the more speedily the operation is performed the less chance will there be of shock resulting. Hæmorrhage, quite apart from its being sufficient to cause collapse, is a most important factor in the course of a serious operation, as if severe it throws a fresh and dangerous strain upon the already overworked vaso-motor centres; this is easily seen in the blood-pressure charts where it will be observed that a severe hæmorrhage in the course of a big operation results in a very marked fall in blood pressure which is but slowly recovered from. Interference with important nerve tracts is another important factor but it can be easily overcome by cocaine nerve blocking.

Keeping the patient warm during operations has always been considered an important means of preventing shock and there is no doubt that it is so. The chief reason for this is that the vitality of all the nerve centres is markedly lowered by any reduction in the temperature of the blood below the normal. The great loss of body heat which results from exposure of the peritoneum during abdominal operations makes it very important that precautions should be taken to keep the peritoneum warm during such operations if any large area is exposed. This may be done by the application of hot sterilised towels to the exposed viscera. But the towels only hold heat for a very short time and changing them as frequently as is necessary interferes with the operation and wastes time. I think the best way of keeping the peritoneum warm is by continuous irrigation with hot water or salt solution. The water should be a few degrees above the normal body temperature, say, 105° F. This has the advantage of preventing any loss of heat while at the same time it is a useful method of preventing shock quite apart from its effect upon the temperature and it does not interfere with the operator. Much, I believe, can also be done to prevent the occurrence of shock by careful attention to the nutrition of the patient. The methods of preparing a patient for operation which are now used, though admirable in many ways, may easily, if overdone, tend towards the production of shock.

The preparation of a patient usually consists in free purgation for a day or two before the operation and in starving him just before the operation. Often the patient is given a very light meal on the evening previously to the operation and nothing on the morning of the operation. This may mean that the patient has not had a real meal for 15 or even 24 hours previously to operation and this, combined with the purging, tends to lower the blood pressure considerably and if overdone may pave the way towards the occurrence of shock. This is most particularly the case with old people and children. Children especially cannot stand starvation even for quite short periods of time and the dangers of shock may be greatly increased if vigorous precautions are taken to prevent post-anæsthetic vomiting by starvation. In cases where shock is one of the dangers of an operation aperients should not be used freely and if it is necessary to get the bowels empty this should be done several days prior to operation. And even at the risk of increasing the vomiting easily assimilated food should be administered to within two or three hours of the operation, so that the patient's vital powers are as high as possible at the time of operation. If the operation is a long one it is a good plan to administer nutrient enemata during the operation or immediately after it. Some form of nourishment should certainly be administered as soon as possible afterwards. Subcutaneous feeding is now a well-established practical method and in certain cases might be made valuable use of.

I believe that the methods of treating shock, such as saline infusion, bandaging the limbs, the administration of adrenalin or ergot, &c., which act by raising the blood pressure, are often not utilised at the time when they can be of the greatest service—that is, at the time when the vaso-motor centres are becoming exhausted and before any real symptoms of shock have developed. Much may be done at this period to prevent exhaustion of the vaso-motor centres by raising the blood pressure. Later, when shock has developed and the vaso-motor centres are exhausted or nearly so, it will be a much more difficult matter to treat it. It is only possible, however, to anticipate shock in this way by having a record of the blood pressure kept during the operation so that the first sign of a dangerous fall in the blood pressure can be detected. At the termination of an operation the application of a tight abdominal binder will do much to sustain the blood pressure and is a good routine measure. This is well shown by some of the charts.

The prevention of shock by cocaine nerve blocking.—If we admit that the shock produced by a severe operation upon one of the extremities is caused by the afferent nerve stimuli reaching the vaso-motor centres in the medulla by means of the main nerves of the limb—and there can be little doubt that this is the main factor in the production of shock in major amputations and other extensive operations upon the extremities—it is then at once obvious that if by any means we can prevent these nerve stimuli from reaching the brain we shall by the same means prevent shock from developing. Crile arguing in this way tried blocking the main nerves of an animal's limb by injecting cocaine into the nerve sheath and then subjecting the limb to an amount of traumatism which he knew from experience was sufficient to cause a marked fall in the blood pressure. He found that no fall in the blood pressure occurred in these circumstances, and, in fact, that if the main afferent nerves of the limb were blocked by the preliminary injection of cocaine, no amount of traumatism to the limb caused any alteration in the blood pressure. Crile and Cushing have used this method of preventing shock in clinical practice and a considerable number of clinical observations have been made demonstrating its value in preventing shock. They have shown that such operations as the quartering operation and amputation at the hip-joint can be performed even upon weakly individuals without any fear of shock resulting provided that cocaine is injected into the main nerve trunks previously to their division. Thus Cushing removed the entire upper extremity with the scapula for sarcoma in a man without any sign of shock resulting by cocainising the brachial plexus previously to its division; while an exactly similar operation performed by him without cocainisation of the brachial plexus resulted in shock so severe that it nearly resulted in the death of the patient. In another case he removed the right leg at the hip-joint in a case of sarcoma in a greatly prostrated young man without any signs of shock either during the operation or afterwards. Crile has reported several similar cases. In one case preliminary cocainisation of the brachial plexus sufficed for an interscapulo-thoracic amputation without a general anæsthetic and no shock resulted from the operation. He has also used preliminary cocainisation to prevent reflex nervous effects in operations for the removal of tumours from the neck where the superior laryngeal nerve was liable to be dragged upon and in operation upon the larynx to prevent reflex inhibition of respiration

Shelton Horsley reports the case of a boy, aged 14 years, whose constitution had been seriously undermined by prolonged sickness and suppuration and who had amputation at the hip-joint performed without any signs of shock developing after preliminary cocainisation of the sciatic and anterior crural nerves. Before commencing the operation the sciatic nerve was cut down upon and exposed and several minims of a 4 per cent. solution of cocaine were injected into it. The anterior crural nerve was partially infiltrated with a 2 per cent. solution. The amputation was then performed under general anæsthesia. The blood pressure was taken with a sphygmometer at intervals during the operation and at the [illegible] millimetres [illegible] the patient. [illegible] k in spite of the fact that owing to the patient's bad general condition previously to the operation a considerable degree of shock was expected.

A case is reported by Hartwell of the Bellevue Hospital of the removal of the entire upper extremity in a man, aged 55 years, for a sarcoma. This method of preventing shock was adopted, 10 or 15 minims of a 2 per cent. cocaine solution being injected into the nerve trunks five minutes before division of the brachial plexus. The condition of the patient was excellent at the termination of the operation and there was no shock. Gessner reports two cases where the shock following a severe amputation seemed to have been prevented by this method. One was an amputation through the thigh; the sciatic nerve was injected during the operation before division. The other case was one of amputation for chondro-sarcoma of the tibia. No shock occurred in either case. In cases of grave traumatic injury to the extremities where shock is present at the time that the patient first comes under observation this method may be of the greatest value. In such cases shock has already resulted from the afferent impulses conveyed to the brain from the injured area. So long as the mangled state of the limb remains afferent impulses continue from time to time to pass by the nerves to the brain; while some of these impulses cause pain, others cause depressor effects upon the vaso-motor centres. And in this way the shock is made worse or caused if not already present.

It is often advised in such cases that the mangled limb should not be removed by amputation until the shock caused by the injury has passed off. The result of this delay is that the causes of the shock continue to operate and in a certain number of cases the patient dies. Delay merely separates those cases where death is inevitable from those which will anyhow recover, while the cases which are on the border line between death and recovery often by delay lose their one chance of recovery. Immediate operation under ether anæsthesia and with cocaine blocking of the main nerves does not in any way tend to increase any shock that may be present from the initial injury but rather tends to lessen it and undoubtedly enables us to save some of the cases which must otherwise die. Such a case of mangling of the arm and shoulder from a railway accident in which cocaine blocking of the brachial plexus was used successfully in preventing further [illegible] is reported by Crile. [illegible] main nerve trunks may either be cut down upon and injected after the production of general anæsthesia and before commencing the operation, or the nerves may be exposed and injected just previously to their division in the ordinary course of the operation. From five to ten minims of a 4 per cent. solution of cocaine should be used for the injection.

This nerve blocking by cocaine is not the same thing as operating under cocaine anæsthesia. It is used in addition to a general anæsthetic and its object is to prevent afferent impulses from the field of operation from reaching the vaso-motor centres in the medulla. The large nerve trunks of the limb are exposed at an early stage of the operation and cocaine is injected into them. Thus in an amputation of the leg an injection is made into the sciatic and anterior crural nerves before these nerves are divided. In operations performed under cocaine anæsthesia the measures adopted to prevent pain are equally effective in preventing shock. Except as the result of loss of blood shock does not develop in operations performed under cocaine anæsthesia. Operations, however, from which shock is likely to result can seldom be performed under cocaine anæsthesia, as the area involved in the operation is frequently too extensive to be cocainised efficiently without prolonging the operation. In abdominal operations it is not possible to apply cocaine to the peritoneum on account of the large amount of the drug which would be absorbed and which might result in poisoning symptoms. Consequently though pain may be prevented shock cannot be entirely prevented by this means. Clinical experience has shown, however, that abdominal operations performed under cocaine anæsthesia are less liable to result in shock than operations performed in the usual way under general anæsthesia. This is, however, probably in part due to the absence of a general anæsthetic and to the surgeon reducing the amount of his manipulations to the least possible, in order to avoid hurting the patient, factors which all tend to prevent shock.

In spinal cocainisation all afferent impulses from the lower limbs and from the greater part of the abdomen are completely blocked and shock cannot result from operations upon these areas. Spinal cocainisation, however, throws out of action the vaso-motor nerves by which the splanchnic area is controlled. The splanchnic area is consequently no longer under the control of the vaso-motor centres and a great fall in blood pressure results from the loss of blood into this area. Observations with the sphygmometer show that spinal cocainisation results in a considerable fall in blood pressure. In fact, spinal cocainisation itself produces shock quite apart from any operation and many of the bad effects which follow this procedure are in all probability due more to the fall in blood pressure which it causes than in any actual toxic effects of the drug. The method of preventing shock by blocking the main nerves with cocaine is one which should prove of considerable value in many operations where important nerve paths are involved. It enables us entirely to prevent shock in all amputations and might also be valuable in such operations as castration, amputation of the penis, excision of the rectum, and in numerous other operations which are liable to result in shock.

A hypodermic injection of morphine given before the administration of a general anæsthetic decreases the patient's susceptibility to shock during the operation. The action of morphine in preventing shock is probably two-fold; in the first place [illegible] to be induced and maintained [illegible] of the anæsthetic and in the second place by its action upon the nervous system it diminishes the intensity of many of the afferent nerve impulses reaching the vaso-motor centres as the result of stimulation of the peripheral nerves at the field of operation. Crile found in his experiments that in animals where anæsthesia was produced by the combined action of morphine and ether, there was much less susceptibility to shock than in animals where ether anæsthesia alone was used. And he came to the conclusion that an anæsthesia produced by the combined action of morphine and ether allowed more extensive operations and operations extending over a longer period of time to be performed than would ether or chloroform anæsthesia alone. I have several times observed that patients who had been given morphine for the relief of pain previously to a severe operation for intestinal obstruction or peritonitis seemed to stand the operation better than patients undergoing similar operations who had not been given morphine. All this seems to show that a full dose of morphine given just before the commencement of a severe operation is of value in preventing the development of shock.

SUMMARY AND CONCLUSIONS.

Surgical shock is a condition produced by exhaustion of the vaso-motor centres and the resulting great fall in blood pressure. Collapse is a similar condition caused by lowering of the blood pressure from hæmorrhage or paralysis of the vaso-motor centres. In surgical operations shock most frequently results from operations upon the abdomen, the most important factors in its causation being injury to, or exposure of, the peritoneum, the length of the operation, injury to organs richly supplied with nerve fibres, as the stomach, uterus, and kidneys, evisceration, and extensive and prolonged manipulations. In operation upon parts other than the abdomen the most important factors in causing shock are injury to large or important nerve trunks or injury to parts richly supplied with nerve endings, the area of the wound, the time of exposure of the tissues, and hæmorrhage.

Another important factor in the causation of shock during surgical operations is the anæsthetic. Ether and the O.E. mixture are the best anæsthetics for cases where there is danger of shock, chloroform on account of the fall in blood pressure which follows its administration being very unsuitable for such cases. The time occupied in performing the operation is always an important factor, more especially in children and old people. The condition of the patient prior to operation is important, especially as regards the condition of his nerve centres. In the treatment of shock stimulants, and especially strychnine, are absolutely contra-indicated as they tend to increase the severity of the condition and to retard recovery. Shock can be produced in an animal by the administration of strychnine alone and it is as reasonable to treat shock by injections of strychnine as it would be to attempt to cure a dying horse by kicking it. The position with the head down and the foot of the bed raised is of considerable value in the treatment of shock and should be more extensively used.

Compression of the abdomen either manually in an emergency or by the application of a tight abdominal binder is a most effectual method of treating shock in all cases. The establishment of an artificial peripheral resistance by the application of external pneumatic pressure affords an absolutely certain method of maintaining the blood pressure, and though not at present a practical method should some day prove of great value. The intravenous infusion of salt solution or physiological serum will raise the blood pressure in all degrees of shock. As a method of treatment in shock it is disappointing as its action is fleeting and it cannot be continued indefinitely. In the collapse of severe hæmorrhage it is effectual and lasting in its effects. The introduction of saline solution into the abdomen at the end of an abdominal operation is a valuable method of combating shock and is not contra-indicated by the presence of pus in the abdominal cavity.

One of the most effectual methods of treating shock that we possess is by the administration of drugs such as adrenalin, hemisine, and ergot which raise the blood pressure by increasing the peripheral resistance independently of the nerve centres. The treatment of shock by the administration of these drugs is as yet in its infancy and only a small number of cases have so far been treated in this way. The experimental evidence is, however, very complete and the few clinical cases where these drugs have been used are very encouraging. The use of these drugs instead of the stimulants which are now so popular, but which have been shown to be useless, will probably result in many lives being saved.

Like sepsis, shock can be prevented much more easily than it can be cured, and as is the case with sepsis so with shock. It is to the careful prevention of shock rather than to its treatment that we must look to get rid of this source of danger in the operations of the future. With the exception of abdominal operations the method of blocking the main nerves with cocaine seems to afford us a ready and most efficient way of completely preventing shock in even the most severe of surgical operations. Morphine, administered both before an operation and afterwards, is a useful aid in the prevention of shock and does not seem to have been used in this connexion as much as it deserves to be. Much may be done to prevent shock by having a chart of the blood pressure kept during all severe operations; procedures which are harmful may thus be avoided, treatment may be commenced at the time when it can be of most value, and, in fact, shock can be thus prevented or treated upon scientific lines.

I believe the best line of treatment in the event of shock occurring or threatening during an operation to be as follows. If the operation is an abdominal one the peritoneal cavity should be filled before being closed with physiological salt solution and if a severe degree of shock is already present hemisine or adrenalin should be added to this solution in the proportion of 1 in 40,000. Whether the operation be an abdominal one or not a firm, tight abdominal binder should be applied at the end of the operation and in bad cases the limbs should be firmly bandaged from the extremities upwards in addition. When the patient has been put back to bed the foot of the bed should be raised at least 12 inches on blocks and all pillows should be removed from beneath the head; the patient should be kept warm and some good form of nutrient enema should be administered and repeated in a short time. No stimulants should be given. A hypodermic injection of aseptic ergot should be given at the earliest sign of shock and repeated if any improvement in pulse tension follows its administration. Except where absolutely contra-indicated an injection of morphine should be given at the end of the operation, whether pain be present or not; and if there is any restlessness afterwards the morphine should be repeated. If, in spite of these measures, the blood pressure remains low and the patient continues in a dangerous condition of shock a solution of adrenalin in physiological salt solution in the proportion of 1 in 20,000 [illegible] infused at a rate of about three to five cubic centimetres per minute. The intravenous infusion should be continued until on stopping it the blood pressure is found to remain at a safe level. In bad cases it may be necessary to continue the infusion of adrenalin for a long period but it affords a certain method of maintaining the patient's blood pressure and therefore his life.

In collapse following severe hæmorrhage intravenous infusion with physiological salt solution should be performed as soon as possible. The amount of fluid introduced into the veins should be as nearly as possible equal to the amount of blood lost. The subsequent treatment should be the same as for shock. In all forms of sudden collapse, including the collapse of chloroform poisoning, the intravenous administration of adrenalin is of immense value in assisting to restore the patient's life. This drug, by raising artificially the blood pressure, allows the heart and the vital nerve centres to resume their functions very easily. It should prove of great value in resuscitating drowned persons and in other similar emergencies.

I have attempted in these lectures to clear up some of the more debateable points in the causation and treatment of surgical shock and to establish the treatment of this condition on a sound, practical, and scientific basis. There is still much to be learnt and many of the views propounded in these lectures can only become universally accepted after they have stood the test of time and experience. The clinical experience of a few men is not sufficient to establish the value of a new treatment for such a condition as shock and it needs the accumulated experience of many and the searching test of time. I am afraid I have but swept away some of the dust from the doorstep of a great subject but if by so doing I have thrown some light upon the important subject of surgical shock and thereby encouraged others to look further into its mysteries, my labour is not in vain.

PERICOLITIS SINISTRA.[1]

BY H. D. ROLLESTON, M.D. CANTAB., F.R.C.P. LOND.,
PHYSICIAN TO ST. GEORGE'S HOSPITAL.

IN the following brief remarks attention will be specially called to a group of cases, examples of which, not being particularly rare, have probably occurred in the practice of most medical men. Apology is perhaps needed for the title, though it is not mine, but it has the advantage of describing both the nature and the position of the morbid process. In order to indicate the nature of the cases here grouped together it may at once be stated that the condition is like appendicitis or, rather, for the most prominent feature in both is the involvement of the visceral peritoneum, perityphlitis; only it is on the left instead of on the right side of the abdomen.

Like perityphlitis, the cases here grouped together may give rise to different conditions, thus there may be (1) local peritonitis of comparatively slight intensity around the descending colon or the sigmoid flexure; (2) a local abscess in connexion with the descending colon which may eventually burst into the general peritoneal cavity and set up (3) general peritonitis.

1. In the commoner and less severe form the clinical features are often spoken of as fæcal accumulation or impaction and have been described as sigmoiditis or perisigmoiditis. Bittorf[2] described four cases as acute circumscribed sigmoiditis, but since the process is not necessarily confined to the sigmoid flexure the inclusive term of pericolitis sinistra is perhaps more suitable. Hemmeter,[3] however, gets over the difficulty by describing the cases included in the group as sigmoiditis and pericolitis.

The clinical manifestations are briefly as follows. After constipation of some duration the patient experiences pain in the left iliac fossa, usually has a somewhat raised temperature, and may vomit. On palpation there are deep tenderness, muscular resistance, and a more or less cylindrical tumour palpable in the left iliac fossa, features which suggest appendicitis on the left side. Leucocytosis and indicanuria have been noted in some instances (Bittorf). The following is a case of this category:—

CASE 1.—A man, aged 23 years, was admitted into St. George's Hospital under my care on August 18th, 1904, with acute rheumatism. It

[1] A paper read before the Medical Society of London on March 27th, 1905.

[2] Bittorf: Munchener Medicinische Wochenschrift, 1904, S. 147

[3] Hemmeter: Diseases of the Intestines, vol. i, p. 504, 1901.

[illegible] n the hospital with a previous attack, [illegible] fossa, where there were much [illegible] [illegible] ing kept regularly open, the abdomen became natural.

The symptoms are relieved by removing the fæcal accumulation, preferably by repeated enemata at first, and then by purgatives such as castor oil. For the pain Hemmeter recommends an ice bag in the early stages, followed, if swelling persists for four days, by hot poultices.

I have no data from [illegible] forward as to the morbid chan[illegible] *a priori* be supposed that fæcal [illegible] inflammation of the mucous me[illegible] he colon, and so by extension to local peritonitis, and that the process is much the same as that described by Mr. W. Arbuthnot Lane[4] in the ascending colon as the result of chronic constipation. Pal,[5] however, regards the lesion as a primary circumscribed inflammation of the mucous membrane of the colon and not as a pericolitis. Rixford[6] has recorded two cases allied to this class in which inflammation of an appendix epiploica was due to infection conveyed from a neighbouring false or acquired diverticulum of the colon. In his cases the inflamed appendices epiploicæ were palpable as tumours, of the size of a walnut in one case and of a hen's egg in the other, and were removed. It does not appear that there were abscess cavities in the inflamed appendices epiploicæ as there were in Mr. J. Bland-Sutton's[7] cases of fæcal abscesses in appendices epiploicæ due to the passage of small but sharp foreign bodies from the colon in[illegible]'s cases suggest that [illegible] of the descending co[illegible] This explanation would be compatible with the absence of diarrhœa which ordinary inflammation of the mucous membrane of the surface of the descending colon would probably tend to set up, and also with the undoubted fact that pericolitis [illegible] are set up by constipation alone. Marked sacculation of the colon is by no means constant in constipation and it is conceivable that it is only in those cases in which sacculation is present that the conditions favourable to the development of pericolitis are satisfied. It is highly probable that this condition may pass into that of the second category in which there is a localised abscess in connexion with the colon.

2. *A localised abscess* in connexion with perforation of a stercoral ulcer, either in a false diverticulum or in the wall of the colon, may be either intra- or extra-peritoneal, and in both cases may extend widely along the side of the colon, thus resembling the spread of an appendicular abscess. The method of formation of this form of pericolic abscess is analogous to that of a localised abscess above a malignant stricture of the bowel. It appears probable from a case recorded by Mayor[8] that a pericolic abscess due to perforation of a stercoral ulcer may discharge into the colon by ulcerating the coat of the colon from without (exogenous ulceration). A fistulous communication between the bowel and the urinary bladder may also be set up. The clinical features of a pericolic or perisigmoid abscess may be difficult to interpret correctly, especially when no definite swelling can be felt and the diagnosis of carcinoma of the colon is very likely to be made when a mass is palpable.

The t[illegible] ite the formation of intra- ar[illegible] respectively in connexion [illegible] of diverticula in the descending colon.

CASE 2. *Intraperitoneal pericolic abscess.*—A woman, aged 71 years, who had had a femoral hernia for many years, was attacked with [illegible] was admitted, whic[illegible] who has kindly allowed [illegible] l on Nov. 26th, 1903, w[illegible] and sickness. These s[illegible] 18 months but had b[illegible] lays there had been thrombosis of the veins in both legs. On admission there was abdominal swelling rather suggesting ascites with dulness in the flanks, especially on the left side. On Nov. 30th the patient suddenly became much worse, the abdomen became distended, and the temperature, which had never been below 99° F., touched 102°. This was succeeded by diarrhœa and pain in the left flank. The patient remained very ill and a tumour was felt on the left side which was thought to be connected with the pancreas, on Dec. 18th pleural friction was detected over the base of the left lung, and on the 22nd death occurred, preceded by delirium. The necropsy revealed [illegible]

If the presence of an abscess is reasonably certain it should be opened. A fæcal fistula, however, may be expected, and in a case recorded by Georgi[9] fatal peritonitis followed exploratory laparotomy on an abscess close to the sigmoid flexure and due to perforation of a diverticulum.

3. Lastly, rupture of a circumscribed pericolic abscess into the general cavity of the peritoneum may occur and set up fatal perforative peritonitis as in the following case:—

CASE 4.—A man, aged 52 years, was admitted into St. George's Hospital under my care on August 14th, 1894, moribund, from his con-[illegible]

Stercoral or other kinds of ulcers, such as those due to dysentery, either in false diverticula or in the mucous membrane of the colon may of course perforate directly into the general peritoneal cavity and set up diffuse peritonitis. Beer[10] quotes four cases of perforation of a false diverticulum into the general peritoneal cavity.

THE VIBRATING SENSATION IN AFFECTIONS OF THE NERVOUS SYSTEM AND IN DIABETES.

By R. T. WILLIAMSON, M.D. LOND., F.R.C.P.,
ASSISTANT LECTURER ON MEDICINE, VICTORIA UNIVERSITY OF MANCHESTER.

WHEN the foot of a vibrating tuning fork is placed over subcutaneous bony prominences or surfaces in certain parts of the body a peculiar vibrating sensation is felt. If, for example, the foot of a vibrating tuning fork be placed firmly in contact with the ulnar side of the wrist just at the prominence caused by the styloid process of the ulna a peculiar [illegible] ion is felt at the region named [illegible] this sensation is felt through-[illegible] ulna. A similar sensation is felt when the foot of a vibrating tuning fork is placed over the subcutaneous processes or surfaces of many other bones. Attention was directed to the sensation by Egger in France in 1899 and more recently it has been carefully studied by Seiffer and Rydel[1] and by Goldscheider[2] in Germany, by

---

[1] [illegible] Deutsche Zeitschrift für Chirurgie, Band lxviii, p. 5, 1903 [illegible] cxxviii, [illegible] abstract). [illegible] 1904.

Minor[3] in Russia, and by Marinesco[4] in Roumania. To this sensation have been given the names of vibrating sensation, vibrating feeling, and bone sensibility. The sensation is said to be always present in health; it is usually absent when other forms of sensation are lost owing to disease of the nervous system. But it has been pointed out that in tabes dorsalis when ataxia is present the vibrating sensation may be lost, although sensations to tactile impressions, to pain, and to temperature may be preserved.

Space does not permit an account of the observations of others and I wish in this note simply to record the results I have obtained in the examination of a number of cases of nervous diseases and diabetes. I have always employed the *same* tuning fork—a large one about six inches long. (I may point out that the vibrations of some tuning forks are felt much better than those of others and hence there is considerable difficulty in comparing the results of different observers.) At some parts of the body the vibrating sensation is felt much better than at others. For rapid clinical work I have found the following points convenient for examination: the styloid process of the ulna, the internal malleolus, the inner surface and anterior edge of the tibia about the middle of the bone, the anterior superior spine of the ilium, and the middle of the sternum. In all cases examined the foot of the vibrating tuning fork was placed over three regions: the styloid process of the ulna, the internal malleolus, and the inner surface of the tibia about the middle of the bone.

Briefly stated my results were as follows. In 50 healthy men the vibrating sensation was felt distinctly on both sides, in every case at the three regions just mentioned. From these and additional observations which I have made, and from the observations of others, I think we may conclude that the vibrating sensation is always present in health. Of 200 medical patients examined 80 suffered from diseases of the nervous system, 45 from diabetes mellitus, and the rest rom other diseases (diseases of the heart, lungs, abdomen, blood diseases, diabetes insipidus, &c.). In the last group of cases the vibrating sensation was always present. If we add these 75 cases to the 50 healthy persons examined we have a total of 125 individuals who were in good health or who did not suffer either from nervous ailments or diabetes mellitus. In all of these 125 cases the vibrating sensation was distinctly felt at the three regions tested.

As regards the 45 cases of diabetes mellitus and glycosuria I was surprised to find that in a few the vibrating sensation was not felt, though sensation to tactile impressions, to pain, and to temperature was normal. The results in these cases of diabetes mellitus and glycosuria were as follows:—

	Cases.
Vibrating sensation felt distinctly at all three points tested in	30
Felt distinctly over the ulna, but very feeble and distinguished with difficulty over the tibia and internal malleolus in	7
Lost over the tibia or internal malleolus in	8

In the last group of eight cases the exact condition was as follows:—

	Cases.
Vibrating sensation lost over the ulna, tibia, and internal malleolus on each side in	2
Lost over the tibia and internal malleolus, but felt over the ulna on each side in.	3
Lost over the internal malleolus on each side, lost over the tibia on one side, present on the other, present over both ulna bones in	1
Lost over one tibia and internal malleolus, present on the other side, and over both ulna bones in	1
Lost over the internal malleolus on the left side, felt with difficulty over the inner surface of the left tibia; felt distinctly at the same points on the right side and over the ulna bones in	1

All the diabetic cases in which the vibrating sensation was lost or greatly impaired were mild forms of the disease and all of these patients were over 40 years of age.

As regards the 80 cases of diseases of the nervous system, in 65 the vibrating sensation was normal; in 15 it was lost over the internal malleolus and inner surface of the tibia. Amongst the conditions in which it was present may be mentioned paralysis agitans, idiopathic muscular atrophy, erythromelalgia, epilepsy, neurasthenia, hemiplegia from various causes, sciatica, infantile paralysis, acromegaly, &c. Amongst the 15 cases of nervous diseases in which the vibrating sensation was lost (over the internal malleolus and the inner side of the tibia) other forms of sensation were also lost in five. Especially interesting is the fact that in four early cases of tabes dorsalis the vibrating sensation was lost over the internal malleolus and the inner surface of the tibia but other forms of sensation (to tactile impressions, to pain, and to temperature) were normal. In two of these cases there was ataxia; in two both ataxia and Rhomberg's symptom were absent. In several other cases of tabes there was loss of the vibrating sensation along with impairment of other forms of sensation (to pain or touch).

Also of special interest were three cases of spastic paraplegia in which the vibrating sensation was lost over the tibiæ and internal malleoli but other forms of sensation (to touch, to pain, and to temperature) were quite normal. In these cases there were rigidity of the legs with paresis, spastic gait, increase of knee-jerks, ankle clonus, and extensor type of plantar reflex. One of the three cases was probably due to spinal syphilis in the dorsal region of the cord (Erb's spinal syphilitic paralysis); in the other two there was slight ataxia at the onset (? cases of ataxic paraplegia). In a case of lesion of the pons (? limited softening) the vibrating sensation was lost over the left ulna and over both tibiæ. Tactile sensation was impaired over the left side only but both legs were spastic. In a patient, aged 70 years, who came under treatment on account of "numbness of the left hand," the vibrating sensation was lost over the right tibia and internal malleolus but there were no other signs or symptoms of nervous disease.

From these observations I think one is justified in drawing the following conclusions:—

1. In the normal condition the vibrating sensation, tested in the manner described, is probably always present at the three points mentioned.
2. In early tabes it may be lost in the legs before impairment of other forms of sensation occurs and before ataxia or Rhomberg's sign can be detected.
3. In certain cases of spastic paraplegia it may be lost in the legs when other forms of sensation are not affected.
4. In some cases of diabetes mellitus and chronic glycosuria it is lost when sensation in other respects is normal.
5. From these facts it is evident that sensation cannot be declared to be normal until the vibrating sensation has been tested.

Though the loss of the vibrating sensation is a symptom of considerable interest it is at present too early to say what its diagnostic value will be in the future.

Manchester.

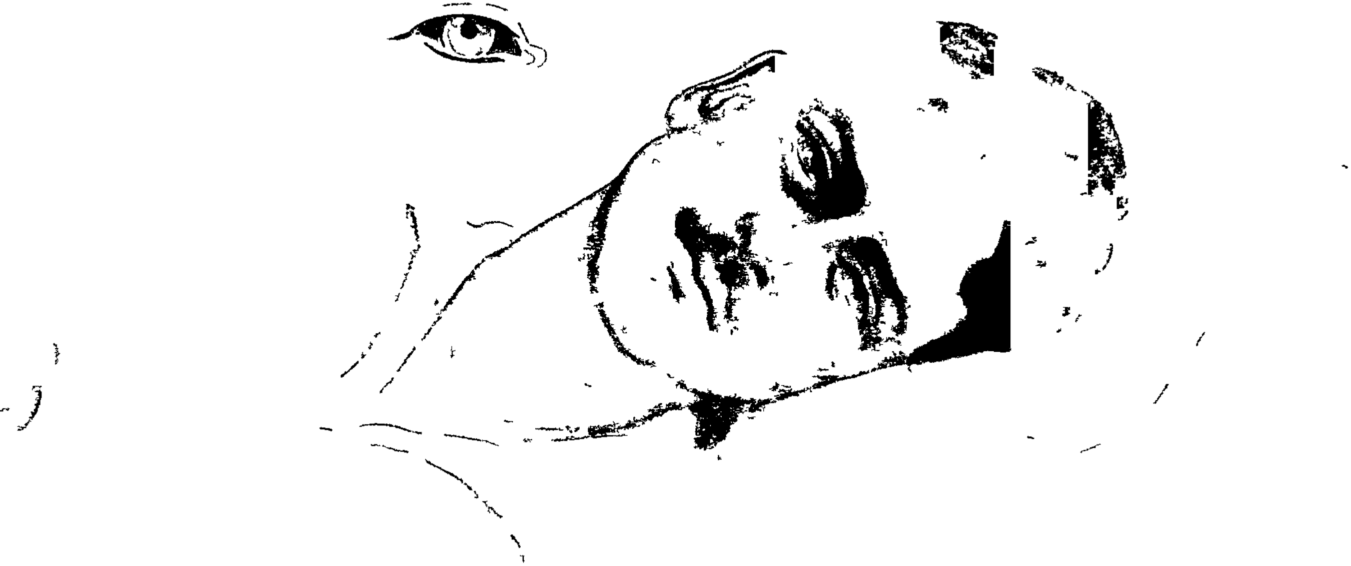
NOTES ON A CASE OF PRESSURE STASIS.

BY R. LANE JOYNT, M.D. DUB., F.R.C.S. IREL.,
SURGEON TO THE MEATH HOSPITAL, DUBLIN.

(*With Coloured Illustration.*)

A MAN, aged 23 years, a fitter, whilst employed in repairs to an electric lift in a large factory got caught beneath the iron counter weight which was descending and an iron bar which ran transversely between the lift guides. The counter weight of over two tons descended on his back, its lower edge, about five inches thick, catching him as he stood upright across both scapulæ; he was doubled down until his bent knees were forced against his chest, his body being prevented from slipping forward by a wire caging and the iron bar beneath him holding his feet. He stated that whilst under the weight he never lost consciousness but became totally blind and remained so until a few minutes after he was released. He heard the men who came to help him talking and repeated their conversation as to what hospital he should be taken to and how. He noticed at once on regaining vision that everything appeared double and that he had dimness of vision in his right eye. He was admitted to the Meath Hospital 20 minutes later and was examined by Dr. W. Boxwell, the house surgeon, and myself. He was in an extreme state of collapse, had a weak thready pulse, and was cold and shivering. His abdomen was quite rigid and hard and his thighs were flexed. He was unable to lie on his back owing to bruising over the spines of the mid-dorsal vertebræ where there was a large effusion of blood. Subsequent x ray examination of his ankles showed that the



TO ILLUSTRATE DR LANE JOYNT'S PAPER ON PRESSURE STASIS

internal malleolus of each tibia had been broken off He had a deep cut on his right shin and a bruise at a corresponding point on the left where the iron bar had met his feet The most marked condition was that of his face which was quite livid the colour varying from isolated red points about the forehead and neck to a dusky red in his ears and cheeks A sharp line of demarcation between the normal and the coloured skin ran across the neck at the level of the thyroid cartilage coursing upwards to the roots of the hair on the nape of the neck Two isolated patches of red minute dots existed in front on the left side below the line of discolouration There was a slight hæmorrhage from his right ear His eyes each showed slight chemosis commencing at the outer and lower quadrant of the sclerotic, this, together with the discolouration of the tissues around the eye, spread in the following two days till no white was any longer visible in the eyes The darkening areola round the eyes contrasted strongly with the colour of his face which began to fade rapidly on the second day It first vanished at the forehead and neck but some red dots showed still, close to the border line The dimness of vision in his right eye ceased in 24 hours and in three days he had no diplopia and stated that he could see as well as ever Shortly after the injury he coughed up some blood stained mucus and for three days had some cough with coarse rales in the chest, this rapidly subsided There was no evidence of fracture of the ribs or vertebral spines He was unable to pass urine for the first 48 hours When first seen, from the rigidity of his abdomen and the collapse it was thought that possibly some rupture of the abdominal organs was present but after the administration of one sixteenth of a grain of strychnine and the placing of hot jars together with pillows so arranged to allow of his very bruised body being comfortable, the shock as well as the rigidity of the abdomen passed off and his pulse never rose beyond 80 Later he was given morphine a few times to relieve the pain in the ankles and shins One week after the date of injury the colour had subsided very much from his face, except from the conjunctiva and neighbourhood of the eyes leaving no stain In ten days the colour of the skin was normal The urine contained neither blood nor albumin From the bloody sputa and mucus it is probable that a condition of ecchymosis must have been caused in parts of the lung but so slight as not to warrant a diagnosis of rupture I am indebted to the house surgeon Dr Boxwell, for obtaining for me the water colour portrait from which the accompanying illustration is reproduced which was executed during the first 24 hours and it shows clearly and without exaggeration the discolouration as then present

In the April number of the "Annals of Surgery" under the title of "Traumatic Asphyxia" was described a very rare condition due to forcible compression of the thorax and abdomen A similar case was recently reported from von Bergmann's clinic Berlin[1] under the title of "Pressure Stasis" The latter title is obviously a more suitable one as being in accordance with the pathology of the case and descriptive of it whereas 'traumatic asphyxia' has an indefinite pulseless ring about it that might be equally well applied to a number of conditions In the paper referred to in the April number of the "Annals of Surgery" Beach has dealt very fully with the so far reported cases and with the pathology of the condition In the last of his cases he excised portions of the discoloured skin and demonstrated that the discolouration is due to mechanical over distension of the veins and capillaries and not to true hæmorrhage This he points out bears out the mechanical theory of Hueter and others While this explanation is true for the greater portion of the face and neck it must be admitted that some of the vessels must have given way or true extravasation have occurred in the lax tissues around the eyes for here the colour changes and pigmentation took place just as in the familiar black eye

The subsequent history of the case here recorded was uneventful and the patient was detained in hospital until his ankles were quite recovered He was subsequently able to walk as well as ever in spite of the double injury That such violent pressure exerted on all the large blood vessels might possibly injure them and so be the starting point of aneurysm was borne in mind and he was finally discharged from hospital with no apparent trace of the violent crush he had received

CARCINOMA OF THE BRONCHUS AND LIVER ASSOCIATED WITH GLYCOSURIA IN A YOUTH

By GEORGE HALL M B Lond, B Sc Durh,
HOUSE SURGEON AND LATE HOUSE PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL

AND

R H TRIBE, M R C S Eng, L R C P Lond,
HOUSE PHYSICIAN TO THE VICTORIA HOSPITAL FOR CHILDREN CHELSEA AND LATE HOUSE PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL

A YOUTH aged 17 years, was admitted on August 10th, 1904 into University College Hospital suffering from cough shortness of breath, and wasting This cough and shortness of breath first began to trouble the patient in the beginning of May, 1904—that is to say, three months previously to his admission—and at the same time it was noticed that he was losing flesh, his condition, however did not seem to have been bad enough to cause any alarm During the next two months the patient became gradually worse and began to expectorate a large amount of frothy sputum which on several occasions was tinged with dark blood In the beginning of July there was intense irritation of the skin—so severe that the patient often scratched himself until he bled, at the same time his appetite which previously had been moderate, suddenly became excessive, 'unnatural' was the term used, and in spite of it he was getting thinner daily Some three weeks later he began to complain of great thirst which nothing could relieve and then noticed that he was passing a very much greater quantity of urine than usual For a few days previously to admission his face and legs became swollen and he looked so ill that he was taken to the Brompton Hospital for Consumption as it was suspected that he was suffering from pulmonary tuberculosis This disease was excluded as the result of examination and the patient was sent on to University College Hospital for admission He had had no previous illness not even any of the usual acute specific fevers, but enjoyed excellent health playing cricket and football regularly There was nothing of importance in the family history

On admission it was seen that the patient was very ill He was extremely wasted and pale with some slight cyanosis, there was no wandering or loss of consciousness The temperature was 100 6° F Both lower extremities were covered with purpuric spots of irregular outline varying in size from that of a pin's head to that of a threepenny piece, many of these had broken down and were suppurating Both feet were œdematous but there was no dropsy elsewhere In the centre of the back over the right scapula close to the anus and on the left arm were swellings loosely filled with fluid discoloured on the surface and somewhat inflamed The respirations were laboured and rapid (48) and the patient was only able to rest when propped up in the bed There was a continuous hard cough and he brought up a small amount of purulent sputum stained with blood On examination of the chest well marked bronchial breathing could be heard at the left apex and in the second intercostal space on that side there were numerous fine rales, these were the only physical signs obtainable in the lungs but a thorough examination was not made as the patient was so ill The pulse was 132 full and bounding in character The heart sounds were normal The upper limit of the liver dulness in the nipple line was the sixth intercostal space and the lower edge of that organ could be felt one and a half inches below the costal margin its surface was irregular The patient was suffering from considerable diarrhœa, the stools were very loose and contained much undigested food The urine was of specific gravity 1037 it was loaded with sugar and gave a faint diacetic acid reaction with ferric chloride

A diagnosis of pyæmia was made owing to the presence of fever the multiple abscesses and the purpura but this opinion was rendered unsatisfactory by the fact that there was sugar in the urine The patient was worse the next day but not markedly so and he did not seem to be in very urgent danger, the pulse was not so good and there was a little more cyanosis However, about 2 P M, whilst his bed was being moved from one side of the ward to the other, he suddenly collapsed and died in a few seconds. Consciousness was maintained till the end.

At the necropsy the condition found was as follows. In the lower lobe of the left lung there was an irregular mass of growth about two and a half by one and a half inches in size. It seemed to originate near the root of the lung and, roughly speaking, to spread down the course of the bronchus of that lobe; it surrounded this structure and in places had invaded and almost occluded it. The lung below was collapsed but the bronchial tubes in this area were not dilated. This mass was adherent to the adjacent part of the pericardium. There were some small deposits in the upper lobe of the same lung but none in the opposite one. There were two small areas of blood-stained infiltration beneath the parietal pleura on the left side but no fluid was present in the pleural cavities. The growth was white and tough on section. In the abdominal cavity there was some blood-stained fluid. The liver was greatly enlarged and weighed 92 ounces, and projecting from its surface were numerous round masses of growth varying in diameter from a quarter of an inch to one and a half inches; none of these masses were umbilicated but the centres of the larger ones were soft. Near the lower edge of the organ was one of the largest of these masses. It was not so regular in shape as the others and its surface was fungating; attached to it and hanging down into the abdominal cavity was a large dark red clot of blood. On section the liver was found to be studded with masses of growth, the smaller being hard and white and the larger soft and breaking down in the centre. The gall-bladder and ducts were normal. Malignant deposits were also found in the retroperitoneal glands and in those of the posterior triangle of the neck. The calvarium contained several small areas of infiltration which appeared both on the inner and outer surfaces of the bone. A very careful search failed to reveal any more growth about the body.

On microscopical examination all the specimens of growth were pronounced by a competent authority to be columnar-celled carcinoma. The pancreas was normal. Thin blood-stained pus was found beneath the areas of discoloured skin above referred to.

In this case there seem to be several points of interest—the youth of the patient and the questions as to which was the seat of the primary growth and whether the glycosuria was due to the accidental association of diabetes mellitus or was due to the presence of growth in the liver. With regard to the former of these questions we are inclined to think that the seat of the primary growth was in the bronchus because the mass of growth in this situation was very much larger than any of the growths in the liver and because the growth in the lung was single (with the exception of one or two very small deposits), whereas the liver was full of disseminated growths of all sizes like the commoner condition seen when that organ is involved secondarily. The presumption is that the dissemination of the growth took place by means of the blood stream and the occurrence of secondary deposits in the calvarium strengthens this view. As to the second point, some evidence is being collected which points to the possibility of glycosuria being caused by various changes in the liver, notably neoplasm and cirrhosis. It is interesting to note in this case that the symptoms usually associated with diabetes mellitus—the large appetite and pruritus—first showed themselves some time after the symptoms due to the growth in the bronchus had established themselves.

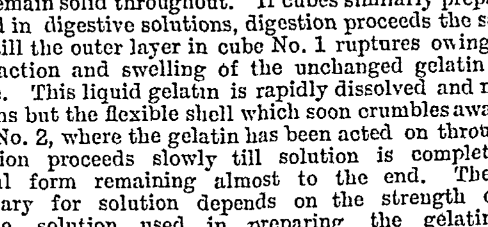
A SOLUBLE BUTTON FOR INTESTINAL ANASTOMOSIS.

BY PETER PATERSON, M.B., C.M. GLASG.,
M.R.C.S. ENG., L.R.C.P. LOND.,
ASSISTANT SURGEON TO THE ROYAL INFIRMARY, GLASGOW.

ONE of the great disadvantages to the use of mechanical supports in performing intestinal anastomosis is the uncertainty that the support will be discharged after it has fulfilled its function, it being sometimes necessary to perform a second operation for its removal. If a button could be obtained which would be easy to manipulate and which would remain *in situ* for the necessary length of time without, in the meantime, injuring the intestine and then undergo solution the principal objection to this method of intestinal union would disappear. After many experiments I have come to the conclusion that gelatin which has been treated with chrome alum meets these requirements, and this material has the additional recommendation that it can be prepared in such a manner as to be more or less resistant to the action of the digestive secretions according to the activity of these in the part operated upon or to suit the particular purpose which the surgeon may have in view. Buttons made of formalised gelatin have been advocated, but unless these are used simply as a temporary adjunct to stitching, they have to be exposed for such a length of time to the action of the formalin that they become indigestible and thus resemble metal supports.

It is a well-known fact that when chromic acid is mixed with gelatin and exposed to light, or when its salts are so used, the gelatin, after a time, becomes insoluble, even in boiling water. As a result of this treatment, however, the gelatin becomes brittle, especially if it has been kept in a moist condition for any length of time before boiling, the degree of brittleness depending on the strength of the chromic solution or the time that this has been allowed to act. Alum, again, hardens gelatin but not sufficiently to prevent its rapid solution in the intestinal secretions; but if chromic acid and alum be combined, as in chrome alum, both insolubility and hardness are produced, whilst the brittleness resulting from the action of chromic acid alone is diminished. When a strong solution of gelatin is gelatinised and a half-inch cube is soaked for from half an hour to an hour in a concentrated solution of chrome alum and then boiled in water it will be found that the surface remains solid whilst the centre becomes liquid. If a similar cube be left in the alum solution for from 12 to 15 hours and be then boiled the mass will remain solid throughout. If cubes similarly prepared be placed in digestive solutions, digestion proceeds the same in both till the outer layer in cube No. 1 ruptures owing to the liquefaction and swelling of the unchanged gelatin in the centre. This liquid gelatin is rapidly dissolved and nothing remains but the flexible shell which soon crumbles away. In cube No. 2, where the gelatin has been acted on throughout, digestion proceeds slowly till solution is complete, the cubical form remaining almost to the end. The time necessary for solution depends on the strength of the chrome solution used in preparing the gelatin and also on the strength of the enzyme employed. If the chrome solution be weak, digestion takes place comparatively fast, even although the mass of gelatin has been permeated by it, whilst if the solution has been strong and has been allowed to act for a considerable time the gelatin becomes almost indigestible. Thus by varying the strength of the solution or the time that this is allowed to act, or by both these means, almost any degree of insolubility can be obtained, though the stronger the solutions the more brittle does the gelatin become. I have found that the most suitable strength for intestinal buttons is 10 grains of chrome alum dissolved in one ounce of *cold* water. The buttons, which are not unlike Murphy's in shape (Fig. 1), are made by pouring a strong watery solution of gelatin into moulds of suitable size, these having been previously lined with a layer of strong muslin or dressing cloth. This fibrous material becomes saturated with the gelatin and incorporated with the outer part of the button and gives additional strength, whilst at the same time diminishing the tendency to brittleness. When the gelatin has set the casts are removed and are placed in the chrome solution, of which there should be an ounce or so for each button. The length

FIG. 1.



of time during which they should remain in this depends on the size of the button and also on the degree of insolubility desired, but casts up to three quarters of an inch in diameter should soak for from 10 to 12 hours by which time the solution will have penetrated the whole mass They are then kept in 50 per cent alcohol till required, the moisture preventing them from drying and so contracting too much whilst the alcohol increases their toughness It is very important to note that when finished the projection on the male part should fit accurately the opening in the female half so that some pressure is necessary to send it home and to increase this adhesion it is better to have the tube made slightly oval in section When this button is exposed to the action of the digestive secretions the gelatin is slowly digested whilst the small piece of muslin collapses and is voided with the intestinal contents A button three quarters of an inch in diameter prepared as described resists solution from five to seven days

The method of fixing this support is almost the same as that employed in using Murphy's button A purse string suture is passed round each end of the divided intestine and the button which has its halves opened but not quite detached (Fig 2) is placed in position and the sutures are pulled tight and tied The two halves are now pressed together and the operation so far as the intestine is concerned is complete If desired a few points of suture may be put in over the support but these are not necessary if the halves fit accurately Considerable force has to be exercised to detach the parts and this resistance to separation is very soon increased owing to the gelatin expanding slightly Should the parts not fit tightly the opening in the female half should be smeared with a layer of thick hydraulic dental cement and the ends then pressed together This cement sets in a very few minutes and firmly solders the button in position To obtain accurate contact of the peritoneal surfaces of the divided intestine the tube of the button should be wide in comparison with its whole diameter otherwise the puckering produced by pulling the running stitch tightly round a narrow tube is so great that the surfaces are prevented from coming into close contact

FIG 2

I have to thank Mr W D Anderson for valuable help and suggestions in moulding and casting the buttons

Glasgow

A NOTE ON A CASE OF GRAVES'S DISEASE

BY W BLACK JONES, M D B S LOND, D P H

THE following case of Graves's disease may be of interest A man aged 38 years consulted me in August, 1904 He had suffered from palpitation for six years but had been much worse for 18 months There was no family history of cardiac trouble On examination both eyeballs were found to be slig[illegible] than the left [illegible] and pulsation [illegible] was slightly [illegible] sixth interspace the cardiac dulness was increased, and on auscultation a soft systolic murmur was heard at the apex and conducted outwards The pulse was of low tension and irregular many of the beats were so weak as not to be perceptible at the wrist The c[illegible] per minute [illegible] the patient [illegible] business, [illegible]

The following treatment was adopted The patient was prescribed a course of the Llangammarch mineral water a glass to be taken three times daily and a course of baths, one on each alternate day He was encouraged to take a moderate amount of exercise including hill climbing He soon began to improve the pulsations were less frequent and less violent and soon subsided to 94 per minute He left after a three weeks course in much better health

In March 1905 the patient reported that he had been steadily improving and that he was quite free from palpitation He can attend to his business without discomfort, walks several miles a day and hunts once a week He had not taken any drugs since he left Llangammarch

The favourable result in this case consisting as it does of a disease that is little amenable to treatment is in my view chiefly due to the balneological methods adopted at this spa The mineral water which has been previously described in the columns of THE LANCET, contains among other ingredients chloride of barium This salt has an action in slowing the pulse similar to that of digitalis and has been shown to be of considerable value in the treatment of various forms of cardiac disease

Ankylostomiasis as it affects Miners

A MEETING of this society was held on March 28th, Sir WILLIAM H BROADBENT being in the chair

Dr THOMAS OLIVER read a paper on Ankylostomiasis as it affects Miners He said that much of what he wished to say was based upon observations made during his trip to Westphalia and Hungary Ankylostomiasis or miners' worm disease while prevalent in the mining districts of mid Europe was known to exist only in one county in England at the present time—viz Cornwall It was not known how the malady was introduced into the Dolcoath mine in Cornwall but as there was a constant stream of miners going there from the colonies and from Europe Asia and America, it must have been carried by infected workmen Considerable uneasiness was being felt in Britain as to the spread of the disease Ankylostomiasis had already formed the subject of reports to the Home Office by Dr J S Haldane and Dr A E Boycott and had in addition formed the basis of a special inquiry by a committee of the British Association for the Advancement of Science It was since the opening of the St Gothard tunnel, 14 or 15 years ago, that Europe had come to realise what a terrible scourge ankylostomiasis was Although the worm was described by Dubini of Milan in 1841 it was Perroncito of Turin who demonstrated the relationship of the anæmia of the miners at the St Gothard tunnel to the ankylostoma duodenale It was until recently believed that the larva of the ankylostoma gained entrance into the alimentary canal by men eating with unwashed hands or by drinking contaminated water but Looss of Cairo, who accidentally infected himself by a culture, had shown that the larva could penetrate the skin and by a circuitous route ultimately reach the upper part of the small intestine This mode of entrance was well shown by the lantern slides exhibited The worm could not reproduce itself in the human intestine Ova were constantly being passed out of the bowel by the fæces Under a favourable temperature (62° to 80° F) and in presence of moisture the ova became transformed into active mobile larvæ These organisms could live for many months in the wet sludge in the mines When the larvæ had reached the intestine and had become transformed into the sexually matured worms, male and female, they attached themselves by their hooklets to the mucous membrane of the bowel from which they received nourishment As several of the ankylostomata especially the females, often contained blood, miners anæmia had been attributed to the blood sucking propensities of the worm but this view was not generally accepted Looss was opposed to it The opinion held by Dr Oliver was that the ankylostomata produced toxins which were absorbed into the circulation of the host and that these, circulating in the blood, induced changes therein such as were met with in anæmia. That ankylostomiasis had been productive of much harm on the continent was shown by the fact that in Westphalia alone it cost the employers and the Miners' Union £100,000 in two years in their efforts to combat the disease. Dr. Tenholt of Bochum, the medical head of the Westphalian Miners' Union, was directing the sanitary measures which sought to exterminate the disease. At one mine Dr. Tenholt had already had 4000 infected miners through his hands. Two years ago, at the Lothringen pit, near Bochum, 70 per cent. of the men were ill from ankylostomiasis, a few months ago only 8 per cent. In Westphalia the compulsory introduction of water sprinkling into the pits was believed to have caused the rapid spread of ankylostomiasis. Hungarian mines were even worse infected than those of Germany. The present position of the ankylostomiasis question in France and Belgium was discussed by Dr. Oliver as also was the preventive and curative treatment of the disease. Preventive measures could be summed up in cleanliness of the workers, the maintenance of a low rather than a high temperature in the mines, and keeping the pits as dry as possible. As regards medicinal treatment by aperients, also by thymol and other intestinal antiseptics, opinions were at variance. One interesting point mentioned by Dr. Oliver was the toxic effects that sometimes followed the administration of large doses of filix mas, as seen in amblyopia which might be temporary or permanent.

Sir **WILLIAM BROADBENT** paid a tribute to the great interest of the paper and referred to the thoroughness with which the investigation of this disease had been carried out. The question as to how the anæmia was produced was still unsettled and further inquiry on this point might yield important information on the subject of anæmias generally.

Sir **PATRICK MANSON** thought it likely that England would at no distant date be invaded by the scourge of ankylostomiasis and that the country might suffer as severely as Germany had done. The disease and its origin only served to emphasise the point that the healthiness of a climate was almost dependent on the presence or absence of parasites. The skin infection and the circuitous route followed by the larva probably allowed the latter to acquire a strong protection against the action of the gastric juice before it reached the stomach and it had been shown that when the parasite was introduced by the mouth it was destroyed by the gastric fluids. In the prevention of the disease a most important point was the education of the miners to a proper knowledge of the methods of infection and of the life-history of the worm. The methods adopted by the Chinese in dealing with fæcal matter were probably effective in preventing the spread of intestinal parasitic diseases. In Sir Patrick Manson's experience thymol never failed to cure the condition but it was most important to give it in large and repeated doses—half a drachm every two hours for several doses. It was necessary to avoid the ingestion of any fluid, such as alcohol, which would dissolve the thymol during the time that the treatment was being carried on. Cases of the disease occurred in Europeans who had lived in the East and were sometimes mistaken for cases of pernicious anæmia.

Dr. **OLIVER** replied.

MEDICAL SOCIETY OF LONDON.

Pericolitis Sinistra.—Epidemic Infective Colitis.

A MEETING of this society was held on March 27th, Mr. **JOHN LANGTON**, the President, being in the chair.

Dr. **H. D. ROLLESTON** read a paper on Pericolitis Sinistra which is published in full at p. 854 of our present issue.—Dr. **F. DE HAVILLAND HALL** remarked that the cases narrated by Dr. Rolleston did not tend to improve the bad reputation which the large intestine had already established among physicians and surgeons. He was inclined to think that the rheumatic diathesis might play a part in the causation of the first group of cases mentioned and he would like to know whether salicylates had been tried. Dr. Rolleston's second group of cases belonged evidently to a different category in which the inflammation was probably of local origin.—Dr. **H. A. CALEY** agreed that cases of pericolitis were generally preceded by chronic constipation but there were probably some cases which supervened suddenly as in one which he quoted and which resulted in acute localised peritonitis. He agreed with Dr. Rolleston that most cases of pericolitis of the descending colon originated in the mucous rather than in the serous coat of the colon. He believed that chronic pericolitis was commoner than was generally supposed. Cases were met with in which besides a history of constipation there was an increased resistance or definite thickening in the region of the sigmoid flexure. Simple colitis was, he believed, much more common than ulcerative or perforative colitis.—Dr. **E. SYMES-THOMPSON**, referring to the therapeutic aspect, said that where there was a tendency to recurrence it was wise to treat the mucous membrane with lubricants, such as vaseline combined with salol, internally.—Dr. **ROLLESTON**, in reply, remarked that the possibility of rheumatism being a factor in the causation of both appendicitis and pericolitis had often occurred to him and he was inclined to agree with the views expressed by Dr. Hall.

Dr. **A. E. CARVER** (Torquay) read a paper on a Series of Cases of Acute Infective Colitis. In the autumn of 1902 there occurred at, or were admitted into, the Great Northern Central Hospital, London, a number of cases of acute colitis. Of only ten of the most severe cases was any prolonged record available. Of these, seven were children between one and a half and nine years of age and three were adults. Of the seven children six were females and one was a male. Of the six females five died and one recovered. The male patient died. Of the three adults all were females, of whom two recovered and one died. The disease had certainly occurred more frequently in children and in them it ran a course as follows. The onset was sudden, consisting of violent diarrhœa with the passage of much blood and mucus. The patient was very quiet and after the first 24 hours the face was flushed, the temperature was slightly raised, and the expression was anxious. The tongue was coated with a thick, moist, white fur, the terminal half inch and the extreme edges being, however, clean and red. Abdominal pain was marked but only before and during the passage of a motion. There was tenderness to a varying extent but most constant over the region of the ascending colon. There was not much change till the seventh or eighth day, when the patient began to show signs of exhaustion, and though the motions became of a pasty, fæcal character about the tenth or eleventh day and no blood was passed after that date, the patient gradually sank and died about the fourteenth to the eighteenth day. In adults the disease ran a milder course. Post mortem the following lesions were often found. There was constantly some enlargement of the mesenteric glands. The walls of the large intestine were much swollen from œdema, and scattered over the surface of the mucous membrane were numerous hæmorrhagic points of about the size of a pin's head. There were also very numerous ulcers, shallow as a rule and circular in outline. The rectum was not affected. Microscopically there was loss of tissue in the mucous membrane to a varying extent; there was also a fairly intense small cell infiltration in the submucous tissue and this had extended to a slight degree into the muscular coat. From the manner in which the disease spread it was evidently of an infectious nature and the evidence seemed to point to water as the agent by means of which the infection was carried, although a diminution in the number of cases and an abatement of the symptoms had been observed when the mothers of the children were instructed to boil the milk. The bacillus enteritidis sporogenes (Klein) was constantly present in the stools. The houses from which many of the cases were drawn were densely overcrowded. Treatment was not very successful.—Dr. **DE HAVILLAND HALL** recalled other epidemics of colitis and the acute colitis associated with Henoch's purpura and other maladies. But the epidemic described by Dr. Carver was of a totally different nature. Here the most striking features were the extreme severity and the high death-rate.—Dr. **C. E. BEEVOR** had had some of the cases under his care. The most extraordinary features were the rapidity of onset and the rapid and fatal issue.—Dr. **E. D. MACNAMARA** referred to an epidemic of colitis having specific characters rather than those of true tropical dysentery which he had observed in Manila, the symptoms of which resembled those of the epidemic described by Dr. Carver.—Dr. **CARVER**. in reply, stated that the death-rate of the severe cases worked out at 60 per cent., but if the milder cases had been included it would probably have been much less.

The **PRESIDENT** announced that the Fothergillian prize for 1905 had been awarded to Sir Frederick Treves.

CLINICAL SOCIETY OF LONDON

The Diagnosis of Gastric Dilatation and Gastroptosis by the X Rays —Stenosis of the Ureter —The After History of Cases of Enterectomy —Streptococcal Pachymeningitis

A meeting of this society was held on March 24th, Dr Frederick Taylor the President, being in the chair.

Dr Norman Dalton and Mr A D Reid communicated a paper on a Method of Ascertaining the Position and Size of the Stomach by Means of the X Rays and a Tube filled with Subnitrate of Bismuth. The method was first used in 1901 but it was only since Mr Reid had succeeded in photographing the stomach tube as it lay in the stomach that the results could be recorded and exhibited. The ordinary stomach tube was passed once a day for two or three days beforehand so as to accustom the patient to its presence in the stomach. The stomach was made empty by washing it out or by withholding a meal. Then with the patient lying on his back the x rays were turned on beneath the couch, an œsophageal tube filled with subnitrate of bismuth being at the same time slowly passed into the stomach while the epigastrium was watched through the fluorescent screen. The position of the umbilicus was indicated by a fixed metal disc and the curve of the ribs *by a metal wire.* In a typical case the tube could be seen to emerge from beneath the ribs a little to the left of the middle line and then to descend until it reached the greater curvature of the stomach rather to the left of the umbilicus. Then the point of the tube slid upwards and to the right along the pyloric end of the greater curvature while the stem became convex towards the left. When the point became arrested at the pylorus the rest of the tube adapted itself to the greater curvature, and the photograph of it in that position gave practically the representation of the greater curvature. Lantern slides taken from the photographs were exhibited, showing the tube in various positions in the stomach. In one case the curve and the position of the tube indicated gastroptosis which was verified at a subsequent operation for gastro jejunostomy. In another case moderate gastrectasis was indicated on the screen and was afterwards found at an operation to be present and to be due to old pyloric adhesions. Subsequent experiments showed that in the cadaver the tube pushed the greater curvature before it so that the point did not ascend towards the pylorus but remained opposite the umbilicus. It was therefore probable that in an extremely atonic stomach the tube would not pass beyond a point corresponding to the umbilicus. In other cases it had been proved at the operation that the curve of the tube gave a faithful delineation of the greater curvature though no photograph of the tube in a normal stomach had yet been obtained because so much of the stomach was covered by the ribs the diaphragm and the left lobe of the liver that the shadow was faint. The method was compared with the injection of air or fluid; it certainly enabled a physician to recommend an operation with the greatest confidence. Mr Reid made some remarks on the technique of taking the skiagrams. The Crookes s tube was inclosed in an opaque box with an adjustable circular diaphragm placed over a three inch aperture opposite the anode, the smallest diaphragm being used that would include the required area. When the bismuth tube had been inserted as far as it would go the patient was directed to hold his breath and an exposure of from ten to 20 seconds was made the plate being placed on the abdomen. The apparatus must be sufficiently powerful to enable a good skiagram to be taken in this time; that used in taking those exhibited consisted of a ten inch variable primary coil worked off the 100 volt continuous main with an electrolytic interrupter working at 15 ampères on the primary of the coil with either a heavy anode or water cooled tube.—Mr Lawrie H McGavin queried whether the stomach would not be displaced by the tube in a living person as it was in the cadaver.—Sir Dyce Duckworth imagined that such displacement would depend on the pressure exerted. He was more doubtful as to whether the tube followed exactly the greater curvature of the stomach.—Dr Dalton in reply said that the stomach wall might be displaced by the point of the tube but could not be displaced when the tube was lying flat and parallel to the wall. No pressure could be exerted on the stomach wall as the tube at once became curved.

Mr Douglas Drew read notes of three cases of Stenosis of the Ureter upon which he had operated. The first case was congenital narrowing of the upper end of the ureter causing hydronephrosis in a woman, aged 34 years. The treatment consisted of incising the stenosed portion of the ureter and suturing it to the adjacent part of the pelvis of the kidney (pyelo uretero plasty) and resulted in complete recovery. The second case, in a woman, aged 50 years, was of a similar nature, but the narrowing affected the upper four inches of the ureter which was exposed. The kidney itself was but little affected although the pelvis contained 25 ounces of fluid. The condition of the ureter was not remediable—at the same time it did not appear desirable to sacrifice the kidney. The ureteral orifice was enlarged as in Case 1, in the hope that it might be enough to cure the hydronephrosis but within three weeks the tumour made its reappearance. Nephrectomy would be necessary. The third case in a woman, aged 28 years, was one of pyonephrosis from calculi impacted in the ureter. Nephrotomy and ureterotomy were performed and subsequently nephrectomy owing to stenosis of the ureter. After evacuating the pus from the kidney, as no cause was found in the organ to account for the condition the ureter was exposed and a fusiform enlargement was found upon it one inch from the pelvis of the kidney. On incising this three minute calculi (which were exhibited) were found embedded in granulation tissue lining the ureter. The kidney was drained for three months during which time no pus was present in the urine indicating that it was obstructed, and as the sinus would not heal nephrectomy was performed and the patient made a satisfactory recovery. Mr Drew remarked on the importance of exploring the ureter in cases of hydro and pyo nephrosis when the cause of the condition was not found in the kidney.—Mr A E J Barker agreed as to the rarity of stenosis in the lower part of the ureter. He had however, operated on several cases of stenosis in the upper part and had split the ureter from the renal end but he advocated the passage of a long catheter from the pelvis of the kidney into the bladder so as to maintain a wide lumen.—Mr W G Spencer asked why the term congenital should be applied where symptoms had appeared so late in life and he suggested the possibility of inflammatory and other causes especially in women where the stenosis might be due to inflammation after labour.—Mr Drew, in reply, justified his use of the term congenital and stated that there was no evidence or history of sepsis in his cases.

Mr Barker read a paper on three cases illustrating the Condition of the Small Intestine after Extensive Enterectomy. They showed that the condition of paresis of the intestine commonly seen about an acute obstruction was not completely relieved by the release of the constriction, but might persist more or less for years a point apparently hitherto overlooked. The first two cases were operated on respectively two and a half years and 21 months before a second operation involving laparotomy had to be done. In both large tracts of small intestine had to be removed and each showed at the second operation that the bowel above the anastomosis had not returned to its normal size or activity as contrasted with the part below the junction. Mr Barker attributed this weakening and thinning of the proximal portion not only to the distension of the gut above the obstruction but to the saturation of all the coats and nerves with toxins developed in the fermenting bowel contents. The third case which had been operated on two years before for obstruction showed the same condition; the obstruction was not relieved but *the small intestine was attached to the* sigmoid flexure. There was in this case clear evidence of atony of the bowel and thinning of its walls two years later when the second operation was performed.—Mr J D Malcolm asked whether the existence of a cicatrix in the intestinal wall might not be a cause of distension and paresis owing to its interference with peristalsis.—Mr Spencer remarked on the extensive resections (in one case amounting to six feet) which had been performed and advocated bolder and more extensive resection on the proximal side of the injured gut especially after gangrenous conditions.

Sir Dyce Duckworth and Dr C M Hinds Howell communicated a case of Streptococcal Pachymeningitis. The patient a boy, aged 14 years was admitted to St Bartholomew s Hospital on Nov 14th 1904 under Sir Dyce Duckworth. There was a history of 18 days' indisposition, with headache and occasional vomiting previously to his admission. The temperature on admission was 102° F. and the pulse was 90. The patient was very irritable and complained of pain behind the left ear, and the head was drawn down slightly to the left but nothing abnormal was found on examination of the ears. A trace of albumin was present in the urine throughout. Nothing abnormal was noted in the nervous system excepting a diminution of the knee-jerks. On Nov. 21st there was an increased amount of albumin in the urine, with blood and casts, leucocytosis amounting to 15,400 per cubic millimetre, and slight twitchings of the face; the cerebral irritation had increased. On the 24th there were Cheyne-Stokes's breathing, paresis of the right side of the face, and ankle clonus, with Babinski's and Kernig's signs. Dyspnœic attacks followed on the 25th and the pulse became irregular. On the 27th the patient became comatose and died. The temperature between Nov. 14th and 23rd was generally about 103° F., but it fell during the last two days of life. The pulse frequency was about 80 to 90 throughout, only becoming irregular towards the end. The post-mortem examination showed a large quantity of pus over the vertex of the brain, sub dural in position, the pia-arachnoid being natural. The lateral surfaces of the brain were deeply depressed and furrowed from the pressure of the pus, which was found bacteriologically to be streptococcal. Pyæmic abscesses were found in the lungs, the kidneys, and elsewhere. The brain was exhibited.—Dr. DALTON mentioned a somewhat similar case in which the nasal sinus had probably been the seat of pyæmic infection; and Sir DYCE DUCKWORTH replied that the nasal sinuses had not been examined in his case.

CHELSEA CLINICAL SOCIETY.

Chronic Constipation and its Medical and Surgical Treatment.

THE annual clinical debate of this society was continued at the Chelsea Dispensary, Manor-street, King's-road, London, on March 21st, Dr. T. VINCENT DICKINSON, the President, being in the chair.

Dr. W. COLLIER (Oxford) said they certainly saw many cases of chronic and persistent headache the basis of which was constipation. They saw also cases of anæmia kept up by constipation and they came across a great number of patients who suffered from symptoms of both mental and physical fatigue, and those symptoms passed off when they paid due attention to their bowels. So that they had a right to conclude that constipation was the cause of a great deal of ill-health. Another very important point was the question of the frequency of the condition in the female sex above 30 years of age and among the poor; he believed at least two-thirds of those who came for treatment suffered from constipation. Another proof of the extreme frequency of constipation was that they had only to turn to the advertisement sheets of their daily press and notice the enormous number of advertisements of quack remedies. With regard to treatment, they might divide their patients into two classes: those who were able to pay for advice and those who were not. Those who were paying for advice they might treat largely without drugs; those who were not able to pay fees they were compelled to treat very largely with drugs. In the treatment of chronic constipation they had two objects in view, they desired to increase peristaltic action and they also wished to increase intestinal secretion. How best could they increase peristaltic action without drugs? He should say one of the best forms of rational treatment was by voluntary movement. On thinking over that subject he was struck by the fact that for the 20 years that he had been in practice he had had to deal with a very large number of rowing men but he could not remember a single rowing man who had ever come to him to be treated for chronic constipation. Why was that? He thought it it was because of the nature of their exercises. If they thought of the action during rowing they saw what happened. The abdomen was intermittently pressed with a certain amount of violence against the thigh muscles. What was the result? He considered that that pressure led to some forcing of bile from the liver into the intestines and bile was a natural aperient and the pressure further increased the peristaltic action. And not only that, but the rowing exercise undoubtedly strengthened the abdominal muscles and those muscles in their contraction also pressed on the intestines. And there they had the keynote of the matter. They could treat chronic constipation largely by voluntary movement. Of course, they could not send all their patients into boats but they could put them on chairs and induce them to go through the same movements as in rowing. Or they could get them to indulge in other movements, such as the squatting movement; that was to say, rapidly and forcibly dropping on to the knees in a squatting attitude and quickly assuming the erect posture again. That did exactly the same thing—it pressed on the liver and also irritated the intestines. They could easily think of other movements having the same object. One movement he was very fond of was to get a person to lie down and to cross the arms on the chest and then raise himself to the sitting position by the contraction of the abdominal muscles. They came next to the question of manipulation and that brought him to speak of massage. He was bound to admit that he thought there was an enormous amount of humbug so far as the treatment of constipation was concerned in the so-called skilled massage. He was a great believer in irritating the abdomen but he did not think it required any skilled masseur. Turning to the question of diet, he thought that their national diet was extremely bad, it was far too dry, too non-irritating. Not half enough fruit was eaten. Another point of importance which had to be considered was the question of fluids. He observed that because many people took alcohol with their meals, they took it in moderation and hence did not get a sufficient amount of fluid. He always paid great attention to the amount of water taken and he suggested the drinking of water at various times of the day. There was one point about water which they ought to remember and that was that most of the English water contained a large proportion of chalk and that chalk in itself was constipating. Therefore when he prescribed water he always took care to suggest that it should be boiled, for in that way much of the chalk became deposited. It might be necessary to supplement the treatment by the use of drugs. A drug of which he was very fond was one which the late Sir Andrew Clark used largely—namely aloes. He was a firm believer in giving aloes in small quantities often repeated, half or a quarter of a grain of aloine, with sulphate of iron and nux vomica, given twice a day about 5 o'clock and 8 o'clock. If that was not sufficient he often gave colocynth. There were some cases in which they wanted to get the stools of a watery nature and in those cases he was inclined to give sulphate of magnesium and sulphate of sodium. He combined those drugs with the liquid extract of cascara sagrada, half a drachm of each. Next as to the question of treatment of the poor. Why was it that the poor suffered so much from constipation? He thought it was largely due to two causes. First of all to the sedentary habits of the people; and secondly, to the fact that their food consisted very largely of white bread and tea. Tea, of course, contained a lot of tannin and the white bread which was eaten in England was not irritating enough. It seemed a monstrous thing that at the hospitals and in private practice they should be compelled to continue to teach people to swallow drugs wholesale in the way that they did, but he was afraid that they would be compelled to continue to do so unless they could alter the national diet and that was a very difficult matter. They could not order the poor to take green vegetables and fruit because of the expense. There was one suggestion which he had tried to induce his poorer patients to act upon and that was to take olive oil for constipation. Olive oil was a good deal cheaper than cod-liver oil, and he found that if people would only try it a few times they would have no objection to it. He thought olive oil was a valuable aperient. And he would ask why should not they endeavour to get people to cook their food in olive oil? When they went to Austria or Spain or Italy they found that nearly everything was cooked in oil, why should not the people in England cook with oil? The probability was that if they adopted that course they would do something to get rid of that national disorder. In treating constipation among the poor it was quite impossible to find time to give them individually the hints he had referred to, and, moreover, he felt quite sure that if he did they would not pay attention to them. Poor people did not care so much for their advice as for their drugs. With regard to the question of an enema, of course, in a troublesome case an enema or two were given, but he had not had much experience of treating patients with enemas over any considerable period. He thought the objection to the enema was that there were a great deal of discomfort and a good deal of time taken up in giving it, and if they could get the bowels to act in other ways it was better for the comfort of the patient The only other remark he would make was with regard to the suggestive paper by Mr Lane He had read that paper with great interest and it certainly, to his mind would add to their interest in the post-mortem room He had never had these changes to which Mr Lane referred pointed out to him before and in the future in examining the dead body of a middle aged person they would be looked for Certainly the suggested operation would have the most stimulating effect upon physicians and general practitioners, because it would impel them to a more active treatment of chronic constipation they would want to preserve their patients from that fate They would also be able to lift the warning finger to patients and say that if they did not carry out their instructions then their fate would be that they would have to hand them over to the surgeon and that a considerable portion of the large intestine would be put completely out of court

Dr F J SMITH said he claimed to have had some experience in the appearances of the abdominal viscera after death but he had never seen the anatomical condition described by Mr Lane He disagreed with Mr Lane's statements in regard to the position assumed by the appendix but agreed with him on physiological points and held with him very strongly that chronic constipation led to symptoms which might in their turn lead to an unendurable continuance of life without relief Modern self consciousness and neuropathy combined with the skill of modern surgeons and the enormously reduced mortality of abdominal operations might possibly have brought many to a position in which they preferred the relief offered at so little risk to a continual worry about their bowels He felt sure that as Mr Lane's *method of relief became more widely known those numbers* would enormously increase The ease the safety, and the simplicity of the treatment offered did not, however forbid

n whether they

to undergo the

ire concerning

the operation and its after effects Concerning simpler measures for overcoming chronic constipation Dr Smith advocated the administration of three or four large enemata of soap and water with olive oil daily He considered that the essential reason why patients drifted into a condition demanding relief by radical measures was that they would not take the trouble necessary to keep free from symptoms Lest he should be taken to be making undue objection to the method suggested by Mr Lane Dr Smith concluded by narrating a case under his care at the London Hospital in which the patient was willing to take the risks of the operation and he had asked his (Dr Smith's) colleague Mr J Hutchinson jun, to see the patient with a view to performing the operation

Dr H CAMPBELL THOMSON limited his remarks to the influences that disorders of the nervous system had in connexion with chronic constipation He explained how the mental state of the patient entered into the question and discussed the close relationship which existed between paralytic affections *of the intestine and the mechanism of secretion* When the paralysis of the intestines was acute as when, for instance it was associated with general peritonitis or intestinal obstruction the secretion was greatly modified both in quantity and quality He could not say with any certainty exactly what modification was produced where paralysis was less complete and of slower onset, but there could be little doubt that changes did take place and that they were not advantageous to the healthy working of the bowel The most obvious examples of paralyses of the intestine were seen in the acute cases some of which as he had shown elsewhere might be also associated with acute paralytic dilatation of the stomach but just as loss of power in a limb might come on rapidly or very slowly according to the cause so might powerlessness of the intestine be found in all degrees of severity and chronicity In many of the severe and long standing cases of constipation which medical measures failed to relieve the loss of power might be of such degree and standing that it was practically irrecoverable and it was for such cases as those that the operation introduced by Mr Lane was likely to be especially beneficial In conclusion

no desire whatever to place

a cause of constipation out

object had been to bring it forward as one of the causes which might, if not recognised sometimes lead to failure of treatment and to such a condition that an operation was at last the only means left by which the functions of the intestine could be restored to health

Dr LEONARD WILLIAMS said that to put the matter shortly, operative measures in the treatment of chronic constipation were not justified until a patient had attained to about the age of 50 years Before that period of life every case of the *malady* was curable by hygienic *regimen* and suitable medicinal treatment After that age the abnormally distended and displaced parts of the abdomen became bound by adhesions into vicious positions and restoration to the normal became impossible without the gentle ministrations of the surgeon and the anæsthetist The essential factors in the production of any case of chronic constipation were deficiency of fluid in the intestinal tract and inadequate peristalsis Deficient moisture in the intestines should be met by the proper management of the skin In discussing the treatment of chronic constipation by partaking largely of foods containing a considerable proportion of indigestible residue Dr Williams pointed out that what the intestines in such cases required was not extra work but physiological rest so that when they did work they might do so to some purpose He emphasised the importance of maintaining in full working order the muscles which formed the external abdominal wall and he had generally found it necessary to prescribe exercises for that purpose After explaining the various exercises which he recommended Dr Williams passed on to discuss the great advantages of the spa treatment in chronic constipation observing that the best subjects for treatment at those spas were as a rule those who were never sent there from this country at any rate—namely, children He then *analysed* in detail the methods in vogue at the different spas and recommended certain prescriptions The object was to educate the intestines to do their work normally and for that purpose the stimulation must be slight and above all things sustained He commented on Kussmaul's oil enema method and mentioned that for the habitual constipation which was liable to occur in old age he had found belladonna to be the best remedy, a quarter of a grain of the extract made into a pill with a quarter of a grain of the extract of nux vomica should be given every night until the bowels could be trusted to act without it

The PRESIDENT briefly thanked those who had taken part in the debate and the proceedings terminated

Procidentia Uteri —Cleidotomy

A MEETING of this section was held on March 10th Dr ALFRED J SMITH the President being in the chair

Mr E HASTINGS TWEEDY read a paper on a Curative Operation for Procidentia Uteri He did not believe that any procedure having for its object the removal of the uterus and the entire closure of the vagina provided a sound surgical remedy He had on three occasions performed an operation that appeared to him on theoretical grounds to fulfil all the requirements of a complete cure in the worst conditions of prolapse Briefly stated the operation consisted of opening into the abdomen both in front of and behind the cervix This enabled the operator to grasp the broad ligaments between the thumb and the forefinger and to protect the ureters and the uterine artery, while the bases of the broad ligaments were denuded by stripping the vaginal mucous membrane of the lateral fornices from them Ligatures were passed through these structures close to their pelvic extremities and these ligatures when tied together in front of the cervix caused the latter to be elevated in an upward and backward direction The basal fibrous structures (Mackenrodt's ligaments) were still further secured in front of the uterus in the neighbourhood of the internal os by several fine sutures The final steps of the operation consisted of amputation of the cervix, anterior vaginal fixation of the uterus and an anterior colporrhaphy combined with a Hegar's colpo perineorrhaphy —Dr J H R GLENN said that the original operator passed the stitch through the back of the cervix and drew it upwards and backwards towards the promontory of the sacrum the fundus falling forwards An anterior fixation was also done —Dr H

JELLETT said that in many cases of prolapse some form of operation was necessary. He was in favour of vaginal fixation and some form of narrowing operation of the vagina. He had no dread of pregnancy afterwards, never having had any trouble. He had lately opened an abdomen in which anterior fixation had been previously done and it had had excellent results. He thought that that operation, combined with narrowing, was usually quite sufficient and if not Mr. Tweedy's operation was an excellent one.—Dr. R. D. PUREFOY said that there was some difference of opinion with regard to the various structures which kept the uterus in position. Dr. Savage had demonstrated that the structures which chiefly prevented procidentia were the utero-sacral ligaments. The procedure which Mr. Tweedy had shown was in certain cases an excellent one but was manifestly not suited to all cases of procidentia. Huguier pointed out that in many cases hypertrophy of the cervix was the cause of procidentia and this could be dealt with by amputation of the cervix.—The PRESIDENT said that he had read the original description of the operation but thought it exceedingly theoretical. He did not see how, in tying the sutures, it was possible to avoid compressing the ureters. He agreed with Dr. Jellett as to the value of vaginal fixation—combined with colporrhaphy—in ordinary cases of prolapse. He had also got good results from abdominal fixation.—Mr. TWEEDY, in reply, said that, like Dr. Purefoy, he had formerly attached great importance to the sacro-uterine ligaments but he had now adopted the view that the ligaments he had pointed out were perhaps of more importance in keeping the uterus in proper position, especially in that of elevation. There was frequently a deep laceration of the cervix in bad cases of procidentia and in such cases Mackenrodt's ligaments were probably torn.

Dr. JELLETT showed an infant on whom Cleidotomy had been performed in consequence of impaction of the shoulders at the pelvic brim. After the operation traction still failed to effect delivery and so the posterior muscular attachments of the scapula were divided. This enabled the whole scapula and shoulders to move forward on to the chest and delivery was then easily accomplished. The fœtus measured 45 centimetres round the shoulder girdle with the shoulders in their normal position and 34 centimetres when compressed after the division of the bones and soft parts. He considered that the use of the blunt hook was difficult and dangerous. In performing the cleidotomy he spent about three minutes over each clavicle and about five minutes in separating the posterior attachments of the scapula. There was no bruising of the maternal parts and the mother's life was never in danger. It did not occur to him to rotate the body, but probably he would have done so if he could have got at the body. It might have brought about the same result as the division of the scapular attachments. The period of gestation seemed in this case to have been prolonged.

EPIDEMIOLOGICAL SOCIETY.—A meeting of this society was held on March 17th, Dr. B. A. Whitelegge, the President, being in the chair.—Dr. A. E. Boycott read a paper on Ankylostomiasis. Some points in the life-history of the parasite were still imperfectly understood but enough was already known for practical purposes. It differed from most in having no "intermediate host" and each species was infective to one animal only, and this only at one period of its saprophytic development, while there was no sexual generation outside the host. One species only, ankylostoma duodenale, attacked man in Europe and Africa, and though Stiles had described an ankylostoma Americanum as a distinct species the differences were but small. The worms were found in the upper part of the jejunum in man in numbers varying from a few to several hundreds, where the female laid numerous eggs easily detected in the fæces. Hatching within 24 hours they passed through three moultings in the course of a week, developing a well-marked chitinous sheath. It was still a sexless larva but had reached the stage of "encapsulation," in which alone it was infective, the eggs or younger larva being swallowed with impunity. So soon as the full-grown larva gained access to the human bowel it underwent rapid development, acquiring, after a renewed series of moultings, male and female sexual organs in different individuals. The larva attained its full growth in about five days and the second period of growth from the encapsuled larva to the reproductive stage occupied about as many weeks, though the encapsuled larva and the perfect worm were each capable under favourable conditions of retaining their vitality for months or even years. In the great majority of cases the larvæ gained access to the intestine of the host per os but the possibility of their penetrating the skin had been established by recent observers. The optimum temperature for incubation and the development of the larvæ was about 24° C. = 75° F., the limits being about 16° C. = 61° F. and the temperature of the blood, but the encapsuled larvæ would live for months at any temperature between 10° and 30° C. Drying and submergence were alike fatal to the eggs but the larvæ required water and while young the presence of oxygen, the absence of which explained their inability to develop in the alimentary canal. The encapsuled larva was, however, capable of living and moving actively for days or weeks in an atmosphere of hydrogen or nitrogen or in vacuo. Their alleged resistance to chemical reagents was apparent only and owing to the protection afforded by the chitinous sheath, for young larvæ were very easily killed and with the encapsuled it was determined not so much by the strength of the solution as by the time required for the penetration of the sheath. The adult larvæ were surely killed in four hours by 0·1 per cent. of sublimate, 0·25 per cent. of izal, or 1·0 per cent. of carbolic acid, and in 24 hours by 4·0 per cent. of sodium chloride or 0·1 per cent. of izal. Some fæces appeared to contain something that inhibited the development of the larvæ, though the eggs were present in great numbers. It was not their chemical reaction and they contained very little soluble salts. Bruns found that the more he diluted the fæcal matter the larger was the percentage of the larvæ reared and aqueous extracts of some fæces would kill the larvæ hatched from others. The essential symptom of ankylostomiasis was anæmia, varying from a reduction of 10 to 20 per cent. in the capacity of the blood for absorbing oxygen to a degree equal to that of the worst cases of pernicious anæmia and, of course, fatal. The direct mortality was considerable but the chronic ill-health and incapacity for work through weakness and dyspnœa were of even greater economic importance. Some men seemed to enjoy a sort of immunity or "impunity," harbouring the worm but presenting no symptoms, though none the less a danger to others. The incidence on the exposed population varied from 2 or 5 per cent. to 75 per cent. in parts of Assam and 100 per cent. in some Cornish mines. The severity of the symptoms depended not so much on the number of the parasites as on their toxicity and this, again, on their more or less favourable surroundings, as moisture and temperature. Thus the Westphalian coal miners were comparatively free until irrigation was introduced with a view to prevent explosions of coal-gas and, on the other hand, the Levant mine in Cornwall, though warmer and filthier than others, was almost alone in its exemption, the floors and walls being saturated with the salt water soaking through the roofs of the galleries running under the sea. They knew enough now to enable them to exterminate this pest from climates where the requisite temperature was met with only in mines and tunnels at great depths, since reproduction was impossible outside of the body and the hatching and growth of the larvæ were equally so within. It was always in their power to expel the parasites by *large* doses of thymol repeated until the eggs had disappeared. In mines and similar places the larvæ would die out spontaneously if not reintroduced and the extinction of those already there could be facilitated by free irrigation with disinfectants. But the most important measure was the prohibition of defæcation except into vessels provided and charged with disinfectants. This, with the medical treatment of men found to be already suffering, had completely saved the workers in the Simplon tunnel from the terrible sufferings of those engaged on the St. Gothard 20 years before and had reduced the percentage of infected men in the Westphalian coal mines from 20 to 3·6, but there was everywhere a residuum of men whom no regulations could coerce and in some places, as the Cornish mines, it was useless to attempt it. In tropical countries, with high temperatures on the surface, the disease was very prevalent, though hitherto unrecognised, and the work of prevention hopeless. Only in the year 1900 did Ashford show that the "anæmia" certified as the cause of 24 per cent. of the deaths in Puerto Rico was due to ankylostomiasis and last year Haldane did the same for the "Dolcoath anæmia," known in Cornwall since 1894 but hitherto unexplained.—In the discussion that followed Sir P. Manson said that in Ceylon the disease was more fatal than cholera and that most tropical anæmia was of the same kind. He believed that the larva entered the body through the skin, especially among people who habitually walked barefooted He had found calomel a valuable anthelmintic —The President remarked that though as yet unknown in the coal mines of Wales and Yorkshire it had recently appeared in those of Lanark —Dr Boycott in his reply stated that in several alleged instances of reproduction out of the body that had been brought under his notice other nematoids had been mistaken for these In experiments *in vitro* dead larvæ were digested but living ones resisted The anæmia was due to the toxins, not to any "blood sucking" or destruction of the corpuscles by the parasites Thymol was incomparably the best anthelmintic, though beta naphthol was very good

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN —A meeting of this society was held on March 17th, Dr L G Guthrie being in the chair —Dr O F F Grunbaum showed a boy, aged nine years, with Alopecia Universalis The hair of the head came out in patches two years ago, complete baldness resulting in one year Then the eyebrows and most of the eyelashes seemed to fade away The nails were normal No cause was found —Mr. G Pernet recommended liberal diet, tonics, thyroid extract, and stimulating lotions —Dr R Hutchison exhibited a case of Late Rickets in a boy, aged nine years For some months the legs had been gradually bending There was marked epiphyseal enlargement of the lower ends of the radius and the ulna, of the knees and the ankles, with typical rickety curvature of the femora and the tibiæ The skull, the chest, and the viscera showed no changes The boy had rickets at the age of three years and had never completely recovered from it —Mr Sydney Stephenson showed a boy, aged nine years with Tuberculosis of the Lacrymal Sac Tubercle bacilli were found in scrapings from the interior of the diseased sac There was a family history of tuberculosis The boy had had enlarged cervical glands treated by operation and still presented *chronic ulceration of the nasal chambers* probably tuberculous —Mr Stephenson also showed a typical case of Keratomalacia in a girl, aged eight months The condition was one of sloughing of the cornea in a young child suffering from marasmus It was rare in England It corresponded with "Hikan," an epidemic disease of Japan, with the ophthalmia Braziliana of South America, and with the destructive keratitis common in Russia during the great *Lenten fast* *The eyes were kept shut, there was no discharge* of muco pus and both corneæ were converted into greyish white sloughs —Dr J Charlton Briscoe showed a girl, aged 13 years, with Tremor of the Right Arm, very rapid, better felt than seen It was absent during sleep, was constant while awake, increased after exertion, and diminished after rest The muscles of the forearm and hand were not involved No other change in the nervous system was found The onset *was sudden*, three months ago, with anorexia and lassitude —Dr Guthrie suggested that the condition was due to a mild encephalitis or thrombosis of some of the finer vessels of the cortex on the left side —Dr G A Sutherland thought the condition "functional, a diagnosis with which Dr Briscoe agreed —Dr F Parkes Weber showed a child, aged 12 years, with Jaundice and very considerable Chronic Enlargement of the Spleen The lymph glands were not enlarged and the blood showed nothing abnormal The mother had had six stillborn children —Mr J Howell Evans showed a case of Osteoma of the Bregmatic Wormian Bone —Dr G S Hett showed a case of Tuberculosis affecting the Lungs, Cervical Glands and Ears —It was discussed by Mr H L Carre-Smith, Dr Sutherland, Mr Howell Evans, and others

ERRATUM —In the report of the last general meeting of the British Laryngological Rhinological, and Otological Association published in THE LANCET of March 25th the first specimen exhibited was said to be shown by Dr Samuel Bradford These words were a misprint for "Dr Samuel Lodge of Bradford"

LEICESTER INFIRMARY —On March 22nd, in the presence of a large and representative assembly, the Marchioness of Granby *opened the new out patient block* of the Leicester Infirmary The waiting hall of the new building is 85 feet long by 29 feet wide and around it are grouped the physicians' and surgeons' consulting rooms, examining rooms for males and females and a small room for minor operations A room is also provided for ear, throat and dentistry cases, with dressing rooms, and there is also a room for ophthalmic purposes with its own small operating room In a recess in the large *hall a refreshment* counter has been provided

Reviews and Notices of Books.

Tent Treatment for the Tuberculous Insane By A E MACDONALD, M D, LL B, Medical Superintendent, Manhattan State Hospital, East Published by the Committee on the Prevention of Tuberculosis of the Charity Organisation Society of the City of New York and the National Association for the Study and Prevention of Tuberculosis 1904

THIS is a brochure reprinted from a directory of institutions and societies dealing with tuberculosis in the United States and Canada Dr MacDonald is, if we mistake not, a pioneer in the matter of tent treatment of the tuberculous insane The annual reports of the Manhattan State Hospital have of late years recorded his experiences and reference has been made to the subject in THE LANCET of Oct 10th 1903, p 1029 He has demonstrated by an experiment covering a period of 40 months at the time of writing that the consumptive insane may be treated to their own advantage and to that of their fellow inmates and attendants throughout the various seasons of the year in this manner The original intention was to remove the patients to the permanent buildings for the winter months but experience showed this to be unnecessary The tents were adequately heated by stoves It is not the purpose of Dr MacDonald's present communication to go into details of the results obtained by tent treatment For these readers are referred to the annual reports of the *Manhattan State Hospital and to special articles* in the *Journal of Insanity* The author here contents himself with stating that the patients suffered no injury or hardship but, on the contrary, benefited, as shown by decrease in the death rate from pulmonary tuberculosis both absolute and relative, and by marked increase in bodily weight of those affected Many persons were discharged to their homes from the tents with the pulmonary disease to all appearances completely arrested, others whose insanity continued were discharged in a like state of arrestation of lung disease to the wards and these latter were still quite well at the date of writing, two years afterwards Incidentally it is mentioned that not only the patients but also the nurses living in the tents enjoyed almost complete immunity from other pulmonary disorders Whereas pneumonia caused 131 deaths in the hospital proper during the three years of tent treatment, not a single case developed in the tents Common colds, also, frequent in the wards and in the attendants home were unknown among the tent dwellers The experience at Manhattan is against the claim for high altitude, for the tents *were located* but a few feet above the tide water level and "the site of the camp is swept in winter by winds of high velocity coming over ice bound waters, and it suffers as much as, or more than, any other part of the city of New York from the trying changes of temperature and humidity which are so characteristic of its climate" The experience at Manhattan would appear to justify the trial of tent treatment in asylums for the insane in this country

---

Atlas und Grundriss der Kinderheilkunde (*Atlas and Rudiments of the Diseases of Children*) By Dr R HECKER and Dr J TRUMPP Munich J F Lehmann 1905 Pp 482 Price 16 marks

THIS new work on the diseases of children is the thirty second volume of Lehmann's series of hand atlases of medicine The authors express in their joint preface the hope that their united efforts may contribute to the understanding of the larger systematic works on pædiatrics and to the management of the more ordinary cases which are met with in general practice They consider that a want of systematic clinical teaching on the subject of the diseases of children in many of the German universities renders the publication of a well-illustrated atlas not only opportune but absolutely necessary if young qualified practitioners are to cope with the varieties of diseases among children which usually form the bulk of their practice. Although it may be questionable whether there is any trustworthy substitute for clinical experience and teaching in the wards, nevertheless we are inclined to believe that a large number of practitioners in Germany will find this little volume not only a valuable substitute but also a useful supplement to the bulky text-books on the same subject which are provided for their use and instruction. The majority of these larger books are so laborious to read and so deficient in illustration that few general practitioners find the time or the opportunity to read them. The little book before us well fulfils its title of atlas. It contains 48 coloured plates and 144 uncoloured illustrations. Certain of both of these groups of illustrations are, perhaps, a little fanciful, out of proportion, and in a few instances quite inaccurate. This is noticeably so in the case of the full-page illustration which presents the skeleton of an achondroplasic individual. In this illustration the length of the head from the apex to the chin is slightly longer than the trunk as measured from the clavicle to the lowest point in the pelvis—proportions which are not only obviously inaccurate but strangely perversive of the truth. Some of the coloured illustrations of the exanthematous rashes and of certain conditions of the skin are not of a very high standard, while that of Koplik's spots is more suggestive of aphthous stomatitis than of the pathognomonic exanthema of measles. Again, on p. 41 appears an illustration of the manner of examining the throats of children. To our mind it represents a method which should be most carefully avoided. The good features of this book apart from the profuseness of the illustrations are, first, the brevity and the conciseness of the general account of the course of the various diseases mentioned and of the ordinary symptoms; secondly, the excellence of the pathological summaries; and, thirdly, the systematic arrangement and the classification of the morbid conditions included in the scheme. Like many other German works, this compilation appears to have been written with painstaking care. It is well up to date and includes an account of most of the recent work in diseases of children. The excellence of the print, of the paper, and of the binding is to be commended.

LIBRARY TABLE.

British Journal of Children's Diseases. Vol. I. Edited by GEORGE CARPENTER, M.D. Lond. London: Adlard and Son. 1904. Pp. 594. Price 15*s.*—The volume under review represents a bound edition of the first 12 numbers of the *British Journal of Children's Diseases.* Considering the short time during which this journal has been in existence it has already met with remarkable success, not only in the number and the variety of the contributions but in the high standard of excellence which characterises many of the original articles, the extracts from current literature, and the illustrations. Among the features of this journal are the publication of signed reviews, the full reports of the Society for the Study of Disease in Children, and the excellent little paragraphs which appear monthly under the title of "Excerpta Puerilia." Two or three of the original articles which appear in this volume are of considerable importance. One of them is by Mr. R. Clement Lucas on an Ill-developed Upper Lateral Incisor Tooth as a Forerunner of Hare-Lip or Cleft Palate and another one is by Mr. J. H. Evans on the Relation of Certain Extra- and Intracranial Hæmorrhages in the Newly Born. The editor and the publishers are to be congratulated on the success of the first volume of this new journal.

Reports of the Society for the Study of Disease in Children. Vol. IV. Edited by GEORGE CARPENTER, M.D. Lond. London: J. and A. Churchill. Pp. 378. Price 12*s.* 6*d.*—The reports of the above society for the session 1903-04 are included in this volume and constitute a compilation of some valuable clinical material. The institution of this society some four years since has unquestionably greatly stimulated the study of the diseases of children in this country and the series of reports which have so far been published provides an acceptable record of many highly instructive and interesting cases which might otherwise have been lost to medical readers. Many of the illustrations are of first-rate excellence and throughout there is evidence of care in the work of editing.

New Streets: Laying Out and Making Up. By A. TAYLOR ALLEN, Engineer and Surveyor to the Portslade-by-Sea Urban District Council. London: The Sanitary Publishing Company. 1905. Pp. 175. Price 3*s.* net.—The avowed object of this work is to serve as a handy book of reference to those engaged in operations conducted under the Public Health Act, 1875 (Section 150), and the Private Street Acts, 1892. It deals with the laying out and making up of new streets and contains plans, specifications, estimates, and apportionments, together with precedents of notices to be served on owners in connexion with the works indicated. As such it will perhaps be found a convenient guide and reminder for those not needing to refer to a bulkier volume or to books dealing more specifically with the subjects comprised. It is a little doubtful, however, whether it can, as the author suggests in his preface, be conceded that instructions given in a condensed form are useful for the guidance of the student. The student is best instructed who performs as much as possible of the boiling down and condensing process for himself. Mr. Allen, in a page of original text, under the heading "Gradients," states that he is "one of the few surveyors who believes that all wide carriage ways, where traffic is considerable, should have the channel in the centre instead of at the sides, thus obviating the tendency of vehicles to slide down the haunches of the road towards the kerb." Why it should be preferable that vehicles should tend to slide towards the centre from the sides of a road he has not perhaps space to explain, nor does he say how drivers who under the usual form of road construction cannot get their horses' feet into the channel, and need not get their wheels into it either, would like the innovation suggested.

The Municipal Year Book of the United Kingdom for 1905. Edited by ROBERT DONALD. London: Edward Lloyd, Limited. 1905. Pp. 622. Price 3*s.* 6*d.* net.—The continual development in all departments of municipal life inevitably involves an extension with every edition to all sections in this book. A brief general review is given of the work of each local authority in alphabetical order, under the name of the city, town, or district, and, wherever possible, the statistical and other information is arranged in a series o special sections in tabular form. A double index—that in the front of the volume and the page numbers for each section at the end of the general summaries—makes the references as simple as it is possible to make them. The practice of interpolating pages of advertisements amongst those of the text appears to us to be an objectionable one. The print of the book is excellent. It is a most useful volume.

MEDICAL EXHIBITION.—We are asked to announce that "a medical exhibition of a high-class and strictly professional character will be held in London during the autumn of this year. The attendance will be strictly confined to medical men, no others being admitted." Particulars can be obtained from the secretary, 44, Bishopsgate Without, E.C.

# Reports and Analytical Records
FROM
THE LANCET LABORATORY.

CERATINE PETROLEUM JELLY.

(PRICE'S PATENT CANDLE CO., LIMITED, BELMONT WORKS, BATTERSEA, LONDON, S.W.)

AN excellent feature of this petroleum preparation is its purity. Consisting entirely of pure hydrocarbons it is free from any liability to become rancid. We have examined both the yellow and the white ceratine petroleum jelly. The white ceratine is absolutely white and the yellow ceratine has the appearance of ordinary vaseline. Ceratine is well adapted for toilet purposes on account of its blandness and purity and in some instances it would serve as an admirable basis for ointments. Ceratine may be procured with or without perfume.

SCOTCH WHISKIES

(WALTER BALLANTYNE AND SONS, ST. BOSWELLS, SCOTLAND.)

We have examined two specimens of whisky of the above firm. The specimen V.O.O. Special Liqueur Highland Whisky proved on analysis to be an all-malt spirit, whilst the specimen marked Finest Old Highland Whisky showed the characteristics of a part-malt spirit. The analysis of the former was as follows: alcohol, by weight 41·55 per cent., by volume 49·02 per cent., equal to proof spirit 85·90 per cent.; extractives, 0·12 per cent.; and mineral matter, 0·03 per cent. The secondary products, given in grammes per hectolitre of absolute alcohol present, were as follows: acetic acid, 36·00; aldehyde, 10·00; furfural, 2·66; ethers reckoned as ethyl acetate, 82·00; and higher alcohols, 200·00: total secondary products, 330·66. These figures coincide with those obtained with a genuine all-malt spirit. The whisky is well matured, possessing a fine delicate flavour in spite of the fact that it is an all-malt spirit. It represents what true matured whisky should be. The analysis of Finest Old Highland Whisky gave the following results: alcohol, by weight 42·29 per cent., by volume 49·81 per cent., equal to proof spirit 87·29 per cent.; extractives, 0·13 per cent.; and mineral matter, 0·02 per cent. The secondary products, given in grammes per hectolitre of absolute alcohol present, were as follows: acetic acid, 48·00; aldehyde, 6·00; furfural, 1·50; ethers reckoned as ethyl acetate, 51·00; and higher alcohols, 100·00: total secondary products, 206·50. These figures indicate a part-malt spirit and it is therefore hardly correct to describe the spirit as Highland whisky, since all whisky produced in the Highlands is all-malt spirit. Nevertheless the blend is a satisfactory one and mild to the taste.

MALTICO.

(THE MALTICO FOOD COMPANY, KINGSTON CROSS, PORTSMOUTH.)

In a previous analytical notice of maltico in THE LANCET of May 23rd, 1903, we pointed out that compared with the solid constituents of human milk the composition was satisfactory except in regard to fat which was deficient. This deficiency has been made good and, chemically speaking, maltico now shows a composition identical with that of human milk, taking, of course, the amount of water in each case into account. A recent analysis of maltico gave the following results: moisture, 3·00 per cent.; mineral matter, 2·70 per cent.; proteid, 15·25 per cent.; fat, 23·40 per cent.; and carbohydrates (chiefly maltose with some dextrin), 55·65 per cent. The average analysis of dried human milk is as follows: mineral matter, 1·70 per cent.; proteid, 12·70 per cent.; carbohydrates (milk sugar), 57·60 per cent.; and fat, 28·00 per [illegible] parison one part of maltico by [illegible] weight of water should give a fluid having approximately the same composition as human milk. The product is satisfactory as regards taste and is very convenient for the preparation of a food for the use either of infants or invalids; its value is increased by the fact that its constituents are very largely soluble in water.

MARSALA WINE (OLD PARTICULAR BRAND).

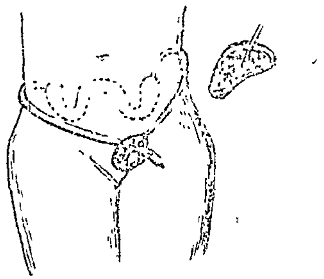
(WOODHOUSE AND CO. AGENTS: COCK, RUSSELL, AND CO., 36, GREAT TOWER STREET, LONDON, E.C.)

Marsala wine partakes of the characteristics of old brown sherry and it is produced much in the same way as are the famous wines of Jerez. The analysis of Marsala wine approximates to that of sherry. Like sherry, it contains a relatively large proportion of vinous ethers, the development of which is encouraged by the use of sulphate of lime in the wine press. The following were the results of the analysis of this specimen: alcohol, by weight 16·46 per cent., by volume 20·24 per cent., equal to proof spirit 35·47 per cent.; extractives, 6·80 per cent.; sugar, 4·64 per cent.; mineral matter, 0·30 per cent. (containing sulphate of potash); volatile acidity reckoned as acetic acid, 0·10 per cent.; and fixed acidity reckoned as tartaric acid, 0·46 per cent. The wine possesses excellent *goût* and is well matured, partaking in this respect of the character of a tawny port.

New Inventions.

RAE'S CURVILINEAR TRUSS.

IN the truss shown in the illustration a firm equable pressure is applied to the hernial orifice by means of a spring in the form of a stout wire about as thick as a quill pen. This spring rises upwards from the pad to just above the hip-bone and passes round to the wearer's back, where it is bent into a shape somewhat resembling the letter W and is comfortably padded as the wide dotted lines indicate. From this point a belt of soft webbing completes the circuit of the body and is hooked to the front pad in the usual way. The maker claims that the pressure can be accurately regulated by bending the spring over the knee in the required direction, for this special kind of wire can be bent without either breaking or losing its tension. Various pads suitable for the different forms of hernia can be supplied and the point of pressure can be adjusted within wide limits by means of screws which fix the pad to the spring. The shape given to the spring is such that no part of it presses on a bony prominence. No understrap is required. The maker is Mr. Richard Rae, 56, Richmond-road, Shepherd's Bush, London, W.



A SPRING STEM PESSARY.

IN our issue of March 4th, on page 578, we drew attention to a new form of pessary, a sample of which had been sent to us by Messrs. S. Maw, Son and Sons. We now learn from that firm that the pessary was originally made at the instigation of Mr. W. Roughton of New Barnet, but with a rigid stem, the novelty claimed for the one described in THE LANCET of March 4th being that it has a flexible watch-spring stem.

THE LANCET.

LONDON: SATURDAY, APRIL 1, 1905.

Peritonitis.

AT the present time inflammation of the peritoneum is considered to be almost invariably the effect of the perforation of a hollow viscus or due to the direct introduction of micro-organisms from without. Formerly it was customary to speak of peritonitis as "brought on by exposure to cold, more especially when the skin has been previously relaxed by a warm atmosphere or by fatigue." It is true that it was recognised that intestinal perforation might cause peritonitis but such an etiology was considered to be rare and therefore comparatively unimportant. Now that it is acknowledged that bacterial invasion is the essential cause of peritonitis it naturally becomes of importance to know to what organisms we are to attribute this inflammation. For it is evident that in all cases the microbic infection cannot be identical seeing that the clinical results differ widely even when the extent of infection is apparently the same. Such an inquiry has been undertaken by a large number of investigators but probably the most complete and elaborate study of the bacteria of peritonitis is that which was undertaken by Mr. LEONARD S. DUDGEON and Mr. PERCY W. G. SARGENT, and which has been described in the Erasmus Wilson lectures recently delivered by them before the Royal College of Surgeons of England and published in THE LANCET of Feb. 25th and March 4th and 11th.

In entering on the study of the bacteriology of peritonitis it was natural that an inquiry should be made into the possibility of the condition which has been styled chemical peritonitis. It will hardly be disputed that theoretically the introduction into the peritoneum of irritating chemical substances might give rise to peritonitis but this is not the point in dispute. The question is whether it is possible for an effusion of blood or other non-microbic fluid to set up an inflammation of the peritoneum without the assistance of any micro-organism. Most observers have answered the question in the affirmative, maintaining that it is possible for the effusion of blood in the peritoneal cavity to set up peritonitis without microbic assistance. Those who have held this opinion have ascribed the inflammation to the fibrin ferment or some other chemical product of the effused blood. In this view the lecturers were unable to concur, for they have investigated twenty cases of intraperitoneal hæmorrhage. Seventeen were the result of extra-uterine pregnancy and in every one of these a white staphylococcus was obtained from the blood clot and of the three remaining cases, in which the hæmorrhage was caused by rupture of the spleen or the liver, two also showed the same staphylococcus, while the third was operated on within two hours of the accident. To this staphylococcus albus Mr. DUDGEON and Mr. SARGENT ascribe great importance and to this point we shall return later, but here we may say that we are inclined to concur in the view that the unvarying presence of this coccus in all intraperitoneal hæmorrhages of more than a few hours' duration which they have examined goes far to justify the ascription of the peritoneal inflammation which occurs to its influence. It is well known that after the rupture of a tubal pregnancy a certain amount of fever is usually present and it is more likely that this pyrexia is due to a bacterium, if one can always be found, than to a toxic chemical substance derived from the blood.

Much evidence has been adduced in these lectures in favour of the view that each etiological variety of peritonitis has its own bacterial flora. In perforating ulcer of the stomach a good deal of uncertainty has existed as to the organisms associated with the resulting peritonitis, though the amount of work which has been done on gastric perforations has not been very great. The pneumococcus has been credited with an important share in the production of perforating gastric ulcer but the evidence in its favour is of no very great strength. Therefore the observations recorded in these lectures are of the greater value as it is evident that much care has been taken in the investigations. The lecturers have isolated a strepto-diplococcus from the edge of the ulcer in every case and in four cases out of seven it has been found in the peritoneal exudate also. The same organism was found in a perigastric abscess and also in a subdiaphragmatic abscess and in the pleural sac of a case in which the diplococcus had been found at the edge of the perforated gastric ulcer. A full account of the morphology, staining reactions, and pathogenic properties of the organism is given and from these it is clear that the coccus cannot be looked upon as identical with the streptococcus pyogenes; a great point in this connexion is the fact that its pathogenic properties are by no means great for in no case did it kill the inoculated animal though it caused severe symptoms for some hours. Again, of the seven cases of perforated gastric ulcer in which it was discovered only two died and in one of these the death occurred on the tenth day from pneumonia and without any peritoneal symptoms. In the other fatal case diffuse peritonitis was found and it is worthy of note that this was the only case in which the presence of the bacillus coli was ascertained. Another subject discussed in these lectures is called by the lecturers septicæmic peritonitis. They apply this term to cases in which the peritonitis is secondary and due to micro-organisms brought by the blood stream, though they acknowledge that there is no absolute proof that this is the mode of infection. In one case a child had "diffuse erysipelas" and on the tenth day signs of peritonitis developed and the child died within 24 hours. Here the streptococcus pyogenes and the colon bacillus were found. The lecturers considered that peritonitis due to the streptococcus pyogenes is generally a septicæmia. When peritonitis is due to this germ the streptococcus is absorbed so rapidly from the peritoneal cavity that death occurs before the tissues are able to offer any response to the attack. A brief account is given of some investigations made to determine which leucocytes play the most important part in protecting the body against micro-organisms introduced into the peritoneal cavity. The results, which somewhat conflict with the views held by most observers, seem to show that the coarsely granular eosinophile cell is one of the most important phagocytes in the early stages of peritoneal infection, while the finely granular polynuclear cell is the chief phagocyte in the later periods of peritonitis.

Perhaps the most interesting and important conclusions at which the lecturers have arrived are those relating to the action of the staphylococcus albus in peritonitis. The adjective pyogenes is purposely omitted from the name as this organism differs in several points from the *staphylococcus pyogenes albus*. It has usually been held that the presence of a staphylococcus albus in a culture from a peritoneal exudate is due to an accidental contamination from the skin but the lecturers have succeeded in obtaining very clear agglutination reactions which go to show that the staphylococcus albus cannot be a mere contamination as at least six days are needed for the production of the reaction. The peritoneum possesses great power of absorption and this has been shown by MUSCATELLO to be due chiefly to the diaphragmatic peritoneum, though the stomata formerly described can no longer be recognised. The absorption of solid particles, such as bacteria, is carried out by phagocytes which appear almost instantly in response to a peritoneal irritant. This normal lymphatic absorption seems to be capable of dealing with a large amount of toxins and bacteria but should any absorption occur through the blood-vessels a rapidly fatal result may ensue and this is the great danger if the peritoneum is damaged. The exudation of fibrin resulting from a bacterial irritation of the peritoneum is, the lecturers hold, distinctly protective seeing that it lessens the absorption of toxic material by the subperitoneal blood-vessels and at the same time it limits the egress of organisms from the intestine. The importance of this in practice is clear. The thorough cleansing of the peritoneum by washing is undesirable, the lecturers hold, and it is, moreover, impossible. Facts are adduced to show that whenever intestinal obstruction occurs, or even an aseptic fluid such as blood is poured out into the peritoneal cavity, a number of organisms rapidly appear, apparently coming from the intestine. The first to make its appearance is usually the staphylococcus albus, an organism of very low virulence; and the lecturers conclude from their observations that it exercises some kind of protective action in peritonitis, chiefly by determining the advent of phagocytes but also by forming adhesions. When the staphylococcus albus has a good start the more virulent colon bacillus possesses much less power because the peritoneum has been prepared to resist it. Of all the micro-organisms found in peritonitis the most virulent appears to be the streptococcus pyogenes and a fatal result is almost certain should it be present. As to the treatment of acute peritonitis it is clear that as it may be due to many different organisms of very different degrees of virulence no uniform treatment is possible. Fortunately, the most virulent infection, that of the streptococcus pyogenes, is rare, for we are at present powerless to treat it, though a multivalent anti-streptococcic serum appears to be the most hopeful method. In the vast majority of cases the colon bacillus is the chief infective agent and therefore it is well to treat most cases of peritonitis of intestinal origin as cases of infection by the colon bacillus. The lecturers suggest that dry sponging applied locally to the affected region is better than washing, which may carry the infection to unaffected parts, while if those remote regions are already infected no amount of washing is likely to be of any avail. When there is a mild infection, as in gastric perforation and intraperitoneal hæmorrhage, the washing should be thorough. As to drainage it is pointed out that in the severer forms, where drainage is most desirable, the presence of much adhesive exudate renders drainage impossible. Investigations such as these, when made with the care which these lectures disclose, are of the greatest value and cannot fail to advance our knowledge of the processes of peritonitis. Caution is, however, necessary. In the application to practice of the theories based on such investigations our bacteriological conclusions must always be tried by the touchstone of clinical experience; by that alone can we be certain of their real value.

Double Consciousness.

AMONGST the most interesting and puzzling of psychical phenomena are those of so-called double consciousness, concerning which there has been considerable discussion in the press lately. This term in its fullest significance connotes something more than a mere modification, impairment, or clouding over of consciousness, such as may occur in various conditions of health and disease (for example, in dreaming and in febrile delirium); it implies nothing less than a dual personality. In a fully developed case of this kind there is a dual existence and the individual in either phase is ignorant of his actions in the other. The events of a particular phase are only recalled with the reappearance of that phase. In the second or altered phase the individual, notwithstanding that his character, manner, and capabilities may be completely altered, conducts himself in a rational and purposeful way. Exceptional cases are on record in which the person affected has remained definitely in the altered or abnormal state, which was superior to the original personality. Usually the abnormal state does not last for more than a few days. Instances are recorded in which a bridge of memory has been supplied between the normal and the altered phases by means of hypnotism, the patient in the hypnotic trance giving a complete history of his proceedings in the abnormal state when previously he could give no account of himself.

Such well-marked examples of dual consciousness as are above referred to are very rare, the separation of the two states being usually less distinct, and the abnormal phase is commonly below the normal in respect of complexity of conduct. Examples, more or less pronounced, of double consciousness are to be met with in somnambulists, in persons hypnotised and under the influence of suggestion, in various forms of insanity, in cases of febrile delirium, in post-alcoholic conditions, in neurotic persons recovering from bodily illness, and lastly, and probably most frequently, in post-epileptic states or states of masked epilepsy. On investigating the history of persons exhibiting the phenomenon it is commonly found that there is a neuropathic inheritance. Amongst the insane cases of altered personality, more or less pronounced, are numerous and the state of altered consciousness varies much in duration. Some notable instances of alternating personality are to be found amongst cases of so-called "circular" insanity, though in these there is little or no interruption in memory. From a medico legal point of view abnormal states of consciousness associated with somnambulism, epilepsy, and hypnotic suggestion, or occurring in neurotic individuals without such association, are of great importance. In 1887 AZAM published an elaborate monograph entitled "Hypnotisme, Double Conscience, et Altérations de la Personnalité," since which time several instances of the last two conditions have been reported in this country in the Proceedings of the Society for Psychical Research and elsewhere.

A very remarkable and carefully studied case of multiple personality was recently reported to this society by Dr. ALBERT WILSON. No less than ten varieties of the abnormal personality were noted. The patient was a girl, aged 12½ years, of healthy parentage, who had herself been healthy in mind and body until she was attacked by influenza, after which the changes of personality manifested themselves. Some of these were complete, others incomplete, some sudden, others gradual in appearance. In some the patient was totally, in all partially, ignorant of her life during other states. Acquirements such as drawing, writing, and also normal faculties present in certain states were lost in others. Whilst in a blind condition the patient developed the faculty of drawing with the aid of touch alone, this sense being enormously increased in delicacy. The character and the behaviour in some states differed widely from those in others. The various phases varied in duration from a few minutes to ten weeks. The normal state gradually became less frequent and of shorter duration till it finally disappeared. The various stages lasted about three years in all, until ultimately a particular abnormal stage was reached in which the patient remained at the date of the report. In this she was intelligent and able to work. The patient, it is important to note, had two or three epileptiform seizures but there was no reason to regard the altered psychical states as post-epileptic. The various manifestations in this case appear from the testimony of competent and independent observers to be undoubtedly genuine. There has been abundant speculation as to the causation of the states known as dual consciousness and dual personality and this is not surprising having regard to the interesting nature of the problem. Theories of vaso-motor disturbances in this or that area or level of the cortex cerebri do not call for serious consideration in the absence of any demonstrable basis and hypotheses which assume that there are different levels of the pyramidal layer of the cortex to which correspond different personalities are on much the same footing. These are merely explanations, *aus der Luft*, plucked from mid-air. Our present knowledge of the physiology of the constituents of the cortex cerebri does not warrant attempts at explanation of the various phenomena of consciousness.

Science in Romance.

ON March 24th there passed away at Amiens, in his seventy-seventh year, JULES VERNE, a man who during his life was in the enviable position of having contributed more than perhaps any one of his contemporaries to the delight and instruction of his fellows. The romance of science has long been a commonplace, but the converse term, the science of romance, is not perhaps always regarded with that intentness which it deserves, for in many instances the prophetic vision of the romance writer has foreseen possibilities which have not been realised until many years later. To refer only to two prophecies. SWIFT'S extraordinary guess at the number and times of rotation of the satellites of Mars was so far opposed to all known astronomical laws as to seem the wildest of hypotheses and yet how wonderfully correct it proved to be. EDGAR ALLAN POE, again, made his HANS PFAAL reach the moon by inflating a balloon with a gas which he extracted from a certain metallic substance by treating it with an acid, which gas was some 37 times lighter than hydrogen and was a constituent of azote. Many years after this was written chemists were startled by the discovery of helion, a gas which, though not a constituent of azote, is found in association with it. Moreover, when first discovered helion was assumed to be lighter than hydrogen. Subsequent investigations have, however, shown that it is twice the weight.

JULES VERNE, though he was perhaps the first modern writer to perceive the possibilities of modern science as an element of romance in fiction, cannot be said to have foreshadowed any great discovery. Submarine boats were not new when he conceived the wonderful *Nautilus* and although submarines are now quite common inventors have not as yet reached Captain NEMO'S success in making electricity from the constituents of sea water. Navigable balloons of a kind have been constructed but they are not worked on the principle of the "*Victoria*" which, as designed by Dr. FERGUSON, rose or fell by expansion or contraction of the contained hydrogen, so that the aeronauts were able to find a current of air blowing in the desired direction, without losing either gas or ballast. But VERNE certainly used scientific facts in a most brilliant manner for the manufacture of exciting stories. Nothing could bear an air of greater verisimilitude in accordance with the canons of science than his story of "From the Earth to the Moon," except perhaps that entertaining history of the voyage through space on a comet which crashed through the earth and bore away a portion of the Mediterranean sea-board, including a fragment of Gibraltar. In "Dr. Ox's Experiment," again, how delightfully he put forth the effect which saturating the atmosphere of a small Dutch town with oxygen had upon the phlegmatic inhabitants. VERNE was never betrayed into making the absurd mistakes into which less scientifically minded writers of romance have been led. We well remember in the early days of the x rays a story about a thief who swallowed a diamond. This was detected by the acumen of an amateur detective who took an x ray photograph of the diamond by using a camera. To say nothing of the fact that x rays cannot be refracted the diamond is the one gem which is transparent to these rays. In medical matters, again, the writer of fiction very commonly goes hopelessly wrong. The anæsthetic, one whiff of which administered by waving a handkerchief in front of the victim's face causes instant unconsciousness, and the mysterious powder made from plants growing in the Andes which at once cures the deadliest diseases, are instances which will occur to anyone who has studied fiction.

But, on the whole, the ideals of ancient philosophers and of romance writers are becoming every day more and more realised. The ever-burning lamp of the ancients has in a manner had its fulfilment in the discovery of radium; the dreams of intercommunication without the intervention of any material substance have been realised by the work of CLERK MAXWELL, HERTZ, MARCONI, and LODGE, while it is not impossible that the so-called magnetic sympathy with which many seventeenth century writers busied themselves may be found before long to have its roots in the "n" rays or some similar form of energy. Radio-activity has upset all preconceived notions of the relations between matter and energy and it may well be that in years to come our children will be able to use forces now undreamt of in the same way in which we nowadays use heat or those forms of electricity which we do to a certain extent understand. No race of flying men like that so graphically described by PETER WILKINS has yet been discovered but it may be that such exist on another planet. The capabilities of knowledge are almost infinite and the wisest man among us is he who is most fully conscious of his own limitations of knowledge.

Annotations.

"Ne quid nimis."

GUY'S HOSPITAL.

Guy's Hospital, as is well known, was founded nearly 200 years ago, or to give exact figures in 1720. In 1828 William Hunt bequeathed a sum of about £180,000 to the hospital and the institution flourished and continued to do good work without any appeal to the generosity of the public until 1884 when owing to falling rents and agricultural depression the income from endowments had diminished by about 50 per cent. At this date the first appeal to the public was made and the principle of making some of the beds "pay beds" was introduced. In 1901 another appeal was found to be necessary on account of the buildings having become out of date and old fashioned. The sum asked for was £180,000 for rebuilding and other improvements and it was further mentioned that £25,000 per annum besides the income from endowments were necessary for the hospital to be kept in full working order. The governors now repeat the appeal of 1901 the response to which, to use their own words, "was inadequate." The necessary works have been carried out but the hospital is £84,000 in debt; its assured income is about £51,000 per annum but its total annual expenditure is calculated at £66,000 per annum. There is thus a deficit of £15,000 per annum for which, as well as for money to liquidate the debt, the governors are now appealing. The hospital has done, and is doing, noble and valuable work so we wish the appeal of the governors of Guy's Hospital every success and hope that the money will be forthcoming.

THE VENTILATION OF THE HOUSE OF COMMONS.

ACCORDING to a report recently presented to both Houses of Parliament the abolition of horse traffic in the streets of London would do much to improve the condition of the air of the House of Commons. There is no doubt that by the exclusive use of motor vehicles the air in all our big towns, and therefore of the houses and offices in these towns, would be made, bacteriologically speaking, much more satisfactory. We say bacteriologically advisedly, because motor-cars in their present form undoubtedly conduce to the pollution of the air with unpleasant and imperfect products of combustion. According to Dr. M. H. Gordon's report on the quality of the air of the House of Commons of the four faults brought to light one only is physical and three are bacteriological. The air supplied to the debating chamber under the present system is altogether too dry. We believe that this physical defect is of far greater importance in connexion with the quality of air than is generally recognised. At any rate, the peculiar and essential quality of air known as freshness is undoubtedly largely dependent upon its humidity and the enervating effects and malaise which follow a prolonged stay in a confined though freely ventilated space frequently have their origin in part in a subnormal state of humidity. Bacteriologically, the air of the House of Commons is faulty in the following directions. First, the air entering at the north inlet is liable to be polluted by dirt detached from the boots of persons walking over the grating fixed above this inlet. Secondly, the air below the floor of the debating chamber is polluted by bacteria derived from Members' boots, and the third source of bacteriological contamination originates in the material derived from the mouths and upper respiratory passages of persons speaking, coughing, or sneezing within it. It seems to us that the only satisfactory way of dealing with the peculiar circumstances of the House of Commons would be to adopt some efficient application of the plenum system, but this would involve, we fear, a serious alteration in the structural arrangements of the House. It is clear that Members' boots are likely to remain a source of contamination so long as the ventilation proceeds from the floor of the House upwards. We cannot agree with the recommendation made by Dr. Gordon that sulphuretted hydrogen should be used in order to test whether certain doors are air-tight. Sulphuretted hydrogen would, of course, be readily detected by its offensive smell, but why use an offensive agent for the test? There are many other substances the merest traces of which can be detected by the sense of smell and besides sulphuretted hydrogen would have a blackening effect upon any metallic adornments in the house or on lead pigments if they should happen to have been used, as is most probably the case.

URINOSCOPY.

UNDER the above heading we publish in another column a letter from a correspondent who informs us that in South Wales there still exist "medicine men" who profess to be able to "read the water." It seems strange in these days of universal education to find that such a mediæval belief still exists and that, moreover, in a country like Wales the zeal of which for education has been so prominently before the public recently. As lately as the seventeenth century books were published giving instructions to the practitioner as to the methods for the diagnosing of diseases by a mere inspection of the urine. Moreover, by an inspection could be told not only the disease but also the age and the sex of the patient. One such book printed in 1599 was called "A Key to Unknown Knowledge or a Shoppe of Fine Windowes," while another treatise was written by Robert Record. There exists also a delightful tract ascribed to Arnold de Villanova, entitled "Cautelæ Medicoum," which shows very well how the mediæval physician looked upon urinoscopy. As for determining the sex that was done by a series of carefully put questions, and finally the author of the tract remarks with charming candour, "The seventh caution is this, and it is one which is often most useful. Very likely you will gather nothing at all from an inspection of the urine. In that case say that the patient is suffering from obstruction of the liver. The person who has brought the urine will then say, 'No, Sir, it's his head or his legs or somewhere else.' Then you must say, 'Well, that comes from the liver or the stomach.' Be sure to use the word 'obstruction' for they don't understand it and it is often very useful that people should not understand what you say." Perhaps our correspondent will be good enough to inform us whether the modern urinoscopist proceeds in the same manner as did his mediæval ancestor. As to the legal aspect of the case all quackery aims at obtaining money under false pretences but practically speaking there is no remedy. One way to stop it would be that which we have recommended over and over again—namely, that all unqualified persons practising medicine for gain should be made to pay a heavy annual fee for a licence.

PLAGUE IN INDIA.

THE information which we were able to forecast for our readers last week with regard to a scientific commission to inquire into the plague in India has now been made public. An Advisory Committee has been constituted by the India Office, the Royal Society, and the Lister Institute, which has for its object the study of the bacteriology of plague. The committee consists of Sir Michael Foster and Dr. J. Rose Bradford, nominated by the Royal Society; Colonel David Bruce and Dr. C. J. Martin, nominated by the Lister Institute; and Surgeon-General A. M. Branfoot, President of the Medical Board of the India Office, who will act as chairman. While we are glad that the Government of India and our legislators at home are at last sufficiently awake to the seriousness of the situation to be attempting to do something we do not view the attempt with much enthusiasm. The terms of reference to the Committee include only the study of the bacteriology of plague, for which purpose, we may add, it is a well constituted body; but no one will expect much from their work that is likely to lead to early administrative measures for the arrest of the disease. This is not said in any disagreeable spirit of criticism. To look to the cause before looking to the cure is a golden rule in scientific medicine, but could not the cause have been investigated some time during the past two or three years, say when the number of deaths per annum was about as great as it now is per fortnight? Now, when the deaths have reached the appalling total of over 1,000,000 in the year, we think that organised administrative measures based upon what is known should be undertaken. They might well be set in motion concurrently with the scientific proceedings of the Advisory Committee.

ACETONURIA IN CHILDREN.

THE significance of acetonuria has been the subject of much research since von Jaksch in 1885 drew attention to its occurrence in a variety of conditions as well as in diabetes —e.g., in certain febrile processes, in malnutrition, in carcinoma, and in some psychoses. In 1888 A. Baginski studied its occurrence in children, hoping to discover in it the cause of the convulsions of rickets, in which hope he was disappointed. He found acetone in the urine of children suffering from various febrile affections such as pneumonia, measles, scarlet fever, and diphtheria. Shortly afterwards Schrack working in von Jaksch's clinic found that diet exerted an influence upon the amount of acetone excreted, since in seven children who were fed on a diet chiefly composed of meat a large increase in the output of acetone was found. More recently the researches of Hirschfeld and Rosenfeld have more clearly elucidated the conditions leading to an increased output of acetone. These observers have shown that a deficiency in carbohydrates is the chief factor concerned and it was this fact that led Hirschfeld to state that carbohydrates were not sufficiently employed in some cases of diabetes. It is now very generally accepted that an insufficiency of carbohydrates in the diet is the cause of the increased elimination of acetone. This fact disposes of the old view that the source of acetone in the body is carbohydrate. Recently doubt has been thrown on the view that its origin is from proteid and the fact that on giving fat or fatty acids to patients deprived of carbohydrates the amount of acetone eliminated is increased renders it probable that fat is the prime source of the acetone. Dr. Ludwig F. Meyer of Berlin has investigated the conditions leading to acetonuria in the infectious fevers in children and has published his results in an interesting paper in the *Jahrbuch für Kinderheilkunde*, Band ii., Heft 3, S. 438, 1905, from which the above historical *résumé* has been abstracted. His own investigations were made in 37 cases of diphtheria, 26 of scarlet fever, and 15 of measles. The urine was examined qualitatively for acetone by means of Legal's test. In normal urines a negative result was obtained with this test, whereas the result was positive in 70·3 per cent. of the cases of diphtheria, in 69·2 per cent. of those of scarlet fever, and in 60 per cent. of those suffering from measles. He also investigated the acetone quantitatively in some of the cases by distilling it off, converting it into iodoform, and weighing the precipitate so obtained which in a few of the cases corresponded to as much as 150–160 milligrammes of acetone per diem. He was also able to demonstrate the presence of diacetic acid and of β oxybutyric acid in those urines with a considerable amount of acetone. Dr. Meyer summarises his conclusions as follows. Acetone, diacetic acid, and β oxybutyric acid are frequently present in the urine of children suffering from acute infectious fevers and are due to carbohydrate inanition; they rapidly disappear on the administration of sufficient quantities of carbohydrates by the mouth. Fat increases the amount of acetone bodies in the urine. Oxybutyric acid is an indication of a more profound disturbance of the processes of oxidation than acetone or diacetic acid. The infectious fevers can, therefore, give rise to a condition of acidosis but not of such a degree that toxic symptoms are to be feared from it, although this acidosis is of similar character and of like origin to that occurring in diabetes and other conditions.

JAMES I. AND TOBACCO.

IT is scarcely to be wondered at, in an age when smoking is universal, that the tercentenary of the publication by King James I. of his "Counterblast to Tobacco" should have been allowed to go by unnoticed. The "Counterblast" was first printed in 1604 and by 1605 had probably been read by most thoughtful people. The King certainly dealt some tremendous blows at the pipe-smokers of his day. Tobacco and the lues venerea both came from America and the royal author impressed on his "deare countrey men" his conviction that the one was an antidote for the other and that to smoke a pipe was to advertise oneself as a sufferer from a virulent and nameless disease. Tobacco he held to be the symbol of national corruption and decline. Like all bad things it came from a mean source. "And now good Countrey men let us (I pray you) consider, what honour or policie can move us to imitate the barbarous and beastly maners of the wilde, godlesse, and slavish Indians, especially in so vile and stinking a custome?" The smokers of Shakespeare's day believed the use of tobacco to be good for the brain. "It is thought a sure aphorisme in the physickes, that the braines of all men, being naturally cold and wet, all dry and hote things should be good for them; of which nature this stinking suffumigation is, and therefore of good use to them. Of this argument, both the proposition and assumption is false, and so the conclusion cannot but be voyd of it selfe." The King continues in this strain for several pages. Manifestly he chiefly hates tobacco because of its smell and one is inclined to wonder whether this was not more pungent in his day than now. When they smoked the Elizabethans and Jacobeans did not mince matters. "For the vanities committed in this filthy custome, is it not both great vanitie and uncleanesse, that at the table, a place of respect, of cleanlinesse, of modestie, men should not be ashamed to sit tossing of tobacco pipes, and puffing of the smoke of tobacco one to another, making the filthy smoke and stinke thereof, to exhale athwart the dishes, and infect the aire, when very often, men that abhorre it are at their repast? Surely smoke becomes a kitchin far better than a dining chamber, and yet it makes a kitchin also oftentimes in the inward parts of men, soiling and infecting them, with an unctuous and oily kinde of soote, as hath been found in some great tobacco takers that after their death were opened."

ACUTE LYMPHATIC LEUKÆMIA IN INFANCY.

ACUTE lymphatic leukæmia is rare in infancy. In the *Boston Medical and Surgical Journal* of Jan. 12th Dr. R. C. Larrabee has recorded a case in a child, six weeks old, which seems to be the youngest age at which the disease has been observed. A girl of this age was taken to hospital. She was the only child of Russian Jews and the family history was negative. She was born on May 14th, 1903. The mother had an easy and normal labour and was attended from the out-patient department of the Boston Lying-in Hospital. At birth the child weighed six and three-quarter pounds and appeared to be perfectly normal. She was breast fed. After the sixth day, as she cried incessantly, the breast feeding was supplemented by a mixture of milk and boiled water. She was taken to hospital on June 25th because of a slight attack of diarrhœa and vomiting of one day's duration. On examination she was found to be fairly developed but poorly nourished, weighing seven pounds and one ounce. The liver was normal. The spleen was felt extending from under the ribs to slightly below the level of the umbilicus; its edge was sharp. Numerous nodules varying in size from that of a pea to that of a marble were felt in the groins and the axillæ. The abdomen was slightly distended, tense, and apparently tender. Examination of the blood on June 27th gave: hæmoglobin, 60 per cent.; red corpuscles, 4,392,000; and white corpuscles, 918,000. A differential count gave: polymorphonuclear neutrophiles, 0·5 per cent.; small mononuclear basophiles (lymphocytes), 93·2 per cent.; large basophiles (large mononuclears and transitionals), 5·9 per cent.; and eosinophiles, 0·1 per cent. The basophile (non-granular) mononuclears, which comprised over 99 per cent. of the leucocytes, were of all sizes, so that the distinction between large and small forms was arbitrary. In some there was considerable protoplasm but in most there was only a narrow rim about the nucleus. Some appeared like free nuclei. A prolonged search revealed very rare normoblasts and equally rare mast cells. There was slight poikilocytosis. The digestive disorder was treated and arsenic was given but even in minute doses it was badly borne by the stomach and had to be interrupted. Although the diarrhœa was only partly relieved the child gained half a pound in weight and appeared to be doing well until July 25th, when she was taken to hospital in a state of collapse, with marked cyanosis, dyspnœa, retraction of the chest in breathing, and other evidence of obstruction of the larynx or trachea. There was no membrane in the throat but in one nostril was a small yellowish mass the nature of which in the child's condition could not be ascertained. The voice was not entirely lost. There were a few small hæmorrhagic spots on the abdomen. The child was immediately admitted for intubation or tracheotomy but she died before anything could be done. A necropsy was not permitted. Leukæmia is much rarer in infancy than in later childhood. In 1900 McCrae collected 13 undoubted cases of acute leukæmia in childhood to which he added one. Only one occurred in an infant. More recently cases of acute lymphatic leukæmia have been recorded at 20 months, 13 months, 12 weeks, 18 months, one year, and nine months. The case reported above ran its course almost without symptoms which would suggest the diagnosis of acute leukæmia. Hæmorrhages into the skin, a frequent symptom, occurred only on the day before death. But for the rule at the hospital to make a thorough physical examination of every patient and to examine the blood in every case presenting enlargement of the spleen or lymphatic glands the case would have been regarded as an ordinary one of summer diarrhœa. The question of the immediate cause of death is difficult. At first the respiratory obstruction was supposed to be due to diphtheria but opposed to this were the facts that the voice was not entirely lost and that no other evidences of diphtheria were present. Perhaps the obstruction was due to enlargement of the thymus which, according to Pinkus, is always present in leukæmia. On the other hand, the obstruction may have been due to leukæmic infiltration of the mucous membrane of the larynx, which has also been observed.

MUNICIPAL DEPÔTS AND THE STERILISATION OF MILK.

THE gradual establishment of municipal milk depôts in this country is bringing very prominently into discussion the question as to what should be the methods upon which such depôts should be conducted. It is now nearly six years since the first milk depôt was established in this country—namely, that at St. Helens by the corporation of that borough in 1899. Other corporations have followed suit with more or less similar methods. In a paper on this subject which Dr. G. F. McCleary, the medical officer of health of the metropolitan borough of Battersea, read at a meeting of the Royal Sanitary Institute on March 25th, he expressed the opinion that the methods adopted in this country are not entirely satisfactory. The necessity for sterilisation should, he thinks, be dispensed with, since mother's milk is not a cooked food and the aim should, therefore, be to supply milk in an uncooked state. The difficulty then arises that if raw cow's milk is to be supplied the whole of the processes involved in the production of that milk would have to be placed under the effective supervision and control of the responsible officers of the sanitary authority. This would mean, of course, that the sanitary authority would have to possess its own cows. In Dr. McCleary's opinion the following conditions in such circumstances could be fulfilled: 1. The municipal dairy farm should be in the country and not too far from the town and the municipal cows should be healthy and should live as much as possible in the open air. The sanitary conditions of the farm should be insured. 2. The cows should be milked in the open air and the whole process of milking should be conducted with the strictest aseptic precautions. 3. Immediately after milking, the milk should be cooled rapidly to a temperature not higher than 40° F.; the milk should be modified if necessary and promptly bottled. 4. The bottles should be packed in ice, placed in a specially constructed motor wagon, and conveyed to the distributing centres in the town. These methods may seem to imply such a strict attention to details as to be beyond practical application but, as Dr. McCleary points out, they are in operation in the city of Rochester in New York State. Precise precautions are carried out at this depôt to sterilise not the milk but everything with which it comes into contact. Another defect of the British milk depôts pointed out by Dr. McCleary is that practically no provision is made for the effective individual medical supervision of the children. There is no doubt, he thinks, that the value of our depôts would be much increased if a regular medical consultation formed part of the work and especially if that consultation were opened to nursing mothers. Finally, Dr. McCleary concludes that (1) municipal milk should not be sterilised milk but clean milk produced under the strictest possible aseptic precautions. For this purpose the cows must be owned by the municipal authorities. 2. Municipal milk should be supplied primarily to three classes of consumers of milk—namely, nursing mothers, children over nine months old (who would not in the natural course of events be breast-fed, or at all events not wholly breast-fed), and infants under nine months for whom breast feeding is impracticable. Lastly, it should be the object of the municipality to increase the number of nursing mothers so as to diminish the number of infants placed in the last category.

A CASE OF TRAUMA OF THE POSTERIOR PART OF THE SECOND FRONTAL CONVOLUTION FOLLOWED BY ATAXIA, NYSTAGMUS, AND EPILEPSY.

AN interesting case was reported to the American Neurological Association and was subsequently published in the *Journal of Nervous and Mental Disease* for February last by Dr. F. X. Dercum, in which a man, aged 24 years, whose family history was good and who enjoyed good health, received a blow on the head from a baseball bat. He was stunned and subsequently lay in bed for some weeks with delirium passing into mental confusion. Examined two months after the injury the condition was as follows. There were two extensive scars in the frontal region, one on either side of the median line, that on the right side being the larger and more serious; there were also present ataxic gait, tremors and ataxic movements of the left hand and arm, nystagmus on lateral movement of the eyes of an irregular and ataxic kind, difficulty in standing on either foot, especially on the left, and intense headache. An exploratory operation in the right frontal region was advised but was refused. About a year after the accident an attack of an epileptic nature, succeeded by severe frontal headache, occurred. The patient was re-examined. The grasp of the left hand was found to be defective and he stood with difficulty on the left foot; there were persistence of tremor in the left hand, ataxia of the left limbs, diminished sensibility of the left arm, and diminution of the left knee-jerk. The condition of the eyes was as before. Rather more than a year after the accident he was operated upon, an osteoplastic flap being removed in the right fronto-parietal region from the border-line of the hair to just behind the Rolandic fissure. The dura mater was yellow and adherent to the pia-arachnoid over an area of from four to five centimetres. The cortex on incision was found to be darker and redder than normal and softened. The posterior portion of the second frontal gyrus was the region specially involved. The patient made a good recovery from the operation and examination from time to time showed improvement in the symptoms. At the final examination, a little over four years after the accident, the condition was as follows: the ataxia was absent, the patient stood well on either leg, the knee-jerks were normal, the tremor in the left hand was disappearing, there was slight awkwardness in movements of this hand, nystagmus was still present on lateral movement of the eyes, there was no feeling of numbness, and headache was rare. No epileptic attack had occurred for over a year and only one was recorded after the operation. The patient was unable to do hard work. The special interest of the case lies in the ataxia and the nystagmus in Dr. Dercum's view. He states that it is known that lesions of the frontal lobe may give rise to ataxia, sometimes bilateral In connexion with the nystagmus it is pointed out that the second frontal gyrus is a centre which stands in direct relation to movements of the eye. But whilst conjugate deviation has been noted in lesions of this region nystagmus has not been previously observed, though reference is made to a similar case of nystagmus reported by Klien at the time of appearance of the above paper. Attention is drawn to the general character of the convulsive seizures although the lesion giving rise to them was limited.

PROPOSED CONFEDERATION OF THE LONDON MEDICAL SOCIETIES.

UNDER the above heading we publish in another column a letter from Sir William S. Church drawing attention to a meeting to be held on April 10th at the Royal College of Physicians of London, at 5 P.M., when the question of the desirability of uniting the central medical societies of London will be discussed. At the annual meeting of the Royal Medical and Chirurgical Society held on March 1st the project was referred to in the President's annual address and was well received by those present and, as we reported last week, on the occasion of the anniversary dinner of the Medical Society of London held on March 15th, it was mentioned by Sir William Church and sympathetically received by his audience. There can be but little doubt, in our opinion, that a confederation of the medical societies of the metropolis would be of great benefit in many ways. We hope that the forthcoming meeting will be largely attended and that a conclusion favourable to confederation may be come to.

THE SUPPLY OF ELECTRICITY.

AN analysis of the accounts for the year ended March, 1904, of the electricity supply undertakings established in the County of London, together with miscellaneous statistics relating to the area of supply, capacity, output, and average price obtained, has been published by the London County Council. The most interesting part of this analysis to the consumer is that which deals with the various prices charged for current per unit by different companies. The medical man, too, who has uses for the current other than that of lighting may well consider under what category he ought to pay—viz., whether that of lighting or of power and heat. In most cases the maximum price which is authorised to be charged for each unit is 8*d.* but in a few instances it is 7*d.* or 6*d.* and in the case of the Chelsea company it is as high as 10*d.* As a matter of fact, in no case in the County of London is the maximum price charged. The methods of charging for current are two. There is the flat rate system whereby current is charged at a fixed rate per unit whether the demand has been regular or intermittent. The maximum demand system appears, however, to be generally the most satisfactory so far as the economical working of an undertaking is concerned, though it is difficult, we fancy, to convince the consumer that this method is an advantage to him. The principle of the maximum demand system is that the rate charged per unit depends on the regularity of the demand. The system involves, in addition to the usual meter, the use of a demand indicator, the purpose of which is to register the maximum demand made for current at any one time during the period (usually a quarter) of the account. It is thus possible to work out the equivalent number of hours per day during which the maximum demand has been maintained and a sliding scale of charges is applied accordingly. The public, however, in general prefer the flat rate as being, perhaps, the more ntelligible method of the two. To give an example, in he case of a certain company the price charged per unit is 6*d.* flat rate or 7*d.* per unit for the first two hours' average laily consumption of maximum demand during two winter quarters and for the first hour's average during summer quarters, and 3*d.* per unit in excess of this consumption. It would be much to their advantage if consumers would give greater heed to the meaning of the charges presented to them and if they would give more attention as to what the consumption of the electric current really means.

THE INSTITUTE OF MEDICAL SCIENCES FUND: A MUNIFICENT GIFT.

THE scheme for building and endowing an Institute of Medical Sciences under the control of the University of London has, as our readers know, received not only the approval and practical sympathy of His Majesty the King but has been favourably received by the medical and lay press and by a very large section of the London teachers of medicine and the allied sciences. Some large donations have been given already by prominent public men but the latest contribution towards the scheme is the most generous that has yet been received. Mr. Alfred Beit has informed the honorary treasurers "that having read the report of the committee appointed by King Edward's Hospital Fund on the financial relations of the hospitals and medical schools and the correspondence and articles thereon in the *Times*, he has decided to increase the amount of his donation from £5000 to £25,000." By this gift Mr. Beit desires to commemorate the great kindness of his friend Dr. Jameson, C.B., the Premier of Cape Colony, and the services of members of the faculty of medicine during an illness from which he has now happily recovered. At the next meeting of the Senate of the University of London a vote of thanks will surely be accorded to Mr. Beit, as has already been done by the Faculty of Medicine (see page 896 of our present issue), but in the meantime we may be allowed on behalf of the medical profession as a whole to thank him heartily.

A CASE OF INTESTINAL ANTHRAX.

AN instance of this, in the United Kingdom at any rate, very rare form of anthrax is recorded in the minutes of the meeting of the Glasgow health committee which was held on March 8th. On Feb. 1st, says Dr. A. K. Chalmers, the medical officer of health, a lead worker died from intestinal anthrax and Dr. Currie made a careful inquiry into the various sources from which the deceased might have been infected. His occupation was the grinding of white lead in *refined* linseed oil and in the course of his work he came into contact with the following substances which under varying conditions have been associated with outbreaks of anthrax. The substances were four—namely, linseed oil, spent oak bark, tallow used for lubricating a machine, and waste with which the deceased wiped his hands. The oil could be excluded because it was refined linseed oil, which during the process of refining is exposed for many hours to a heat sufficient to kill any anthrax spore in about five minutes. As to the spent bark, it is true that cases of anthrax have occurred in association with tan works, but they have arisen from hides before being submitted to the liming process. As the bark is used upon limed hides and the liming destroys the anthrax infection the spent bark could not be held responsible. The tallow was refined tallow which had been rendered at such a heat as to make it free from anthrax and the waste was cotton and jute waste which is not associated with anthrax. Moreover, no case of anthrax had occurred at the works from which these four substances were derived. As to the man's food, it was similar to that which many of his companions had eaten. Among other articles of food he, in common with others, had partaken of part of a pie and of part of a steak, the meat being traced to possible sources of origin but no definite anthrax infection could be traced. The report continues.—

> That many should partake of the dangerous meat and only one should die is not out of accord with the life-history of the anthrax organism. The organism has two forms—the bacillus and the spore. In the interior of infected flesh it exists in the form of the bacillus, and, as the bacillus, it is readily destroyed by the gastric juice. So much is this the case that a whole [illegible] for food in an English city before its [illegible] and yet no deaths from anthrax were [illegible] the flesh. The anthrax spore, on the other hand, is one of the most resistant of living things and is unaffected by the digestive act. If, therefore, a fortuitous circumstance should favour local spore formation in an infective piece of meat, and if this local area of sporulation should escape the full incidence of heat in the process of cooking, a condition is established in the meat by which one consumer may absorb a fatal charge of spores while others who share the flesh with him may escape unharmed. Under such a condition this isolated death may have occurred.

The extreme rarity of this form of anthrax infection in this country is shown by the fact that Dr. J. H. Bell, in his article on Anthrax in "Allbutt's System of Medicine," vol. ii., p. 538, 1897, says: "No such case has been recorded in this country."

THE SMALL-POX HOSPITALS OF LIVERPOOL.

THE Local Government Board has issued a report by Dr. R. J. Reece which furnishes an important addition to our knowledge concerning the influence of small-pox hospitals in spreading this disease among persons living in their neighbourhood. At different times during the recent severe and protracted epidemic of small-pox in Liverpool three isolation hospitals were in use: the small Priory-road Hospital on the eastern edge of the city, the larger Park Hill Hospital in the south, and Fazakerley Hospital which lies outside Liverpool to the north. The first two have large populations resident in their vicinity. Dr. Reece has made an elaborate study of the local incidence of small-pox during the recent epidemic and his report is illustrated by a series of maps showing the houses which were *affected during every fortnight of* the two epidemic years, 1902 and 1903. The result of his inquiries is to show that inhabited areas within a mile of each of the three hospitals have suffered more severely than the city as a whole and that within these hospital areas the dwellings nearer the hospital have sustained a far heavier incidence of small-pox than those further away. He also shows that the exceptional incidence of small-pox within these areas has corresponded in point of time with the use of these hospitals for the treatment of acute cases of small-pox. Evidence of this was afforded in connexion with each of the three hospitals but was most striking in the case of that at Park Hill, which was used only for a comparatively short period, but during that time appears to have occasioned a local outbreak of very exceptional severity among those who dwelt in its neighbourhood. Dr. Reece concludes that the influence of the hospitals has been responsible in material degree for the considerable and sustained prevalence of small-pox in Liverpool in 1902 and 1903. We propose in a subsequent issue to give an account of the interesting data upon which these conclusions have been based.

PUBLIC HEALTH IN JOHANNESBURG.

THERE must be few, if indeed there are any, municipalities equally populous which approach Johannesburg in the disproportion of the sexes. The last census enumeration was made on April 17th, 1904, and from the preliminary report of the census commissioner (Dr. George Turner) it appears that there were 158,580 inhabitants, of whom 118,917 were males and 39,663 were females. The racial distribution was as follows: Europeans or whites, 52,042 males and 31,860 females; and all coloured races, including South African aboriginals and Asiatics, 66,875 males and 7803 females. Whether a community constituted on those lines possesses elements of stability may be an interesting question for sociologists. Dr. Charles Porter, the medical officer of health, in his report on the period from July 1st, 1903, to June 30th, 1904, gives the following as the marriage-, birth-, and death-rates per 1000 among the white or European population: marriage-rate, 28·4; birth-rate, 28·9; and death-rate, 17·2. Among the Asiatics the death-rate was 19·5 per 1000 and among the coloured African races it was 32·4 per 1000. The area of Johannesburg is 52,330 acres and the density of the population is 3·12 persons per acre, but within the area in question Asiatics live in "warrens" which are seriously overcrowded and Dr. Porter recommends the removal of these persons to an "Asiatic location." The chief causes of death in the mortality returns for the white population are diarrhœa and dysentery with 313 deaths, including 207 of children under one year of age, and pneumonia with 171 deaths. "Rock-drill pneumonia," or "miner's phthisis," caused 36 deaths. Among coloured persons who died within the municipal area pneumonia was by far the most fatal malady, causing 762 deaths; tuberculosis of the lungs was credited with 195 deaths; whilst "rock-drill pneumonia," or "miner's phthisis," was registered in only three cases. The death-rate from pneumonia among whites was 2·0 per 1000, while among coloured persons it was 10·2 per 1000. An outbreak of pneumonic plague was recognised in a coolie location on March 19th, 1904, and between that date and June 30th there occurred 24 cases in whites with 12 deaths and 88 cases in coloured persons with 70 deaths. The cases as they arose were transferred to the plague camp which had been prepared in the beginning of 1903 and the coolie location was burnt after the inmates had been transferred to a segregation camp.

THE TREATMENT OF CARDIAC DISEASE BY ELECTRIC CURRENTS.

IN the *Deutsche Medicinische Wochenschrift*, 1904, No. 52, is a contribution by Dr. Paul C. Franze, entitled "The Electro-therapy of Heart Disease in Combination with the Nauheim Treatment." Dr. Franze has carried out a large number of experiments in order to ascertain the effect of electric baths with the alternating sinusoidal current and of the "four-cell bath" with the faradic current on the action of the heart and on the circulation. The former produce, in the majority of cases, an increase in the blood pressure, a diminution in the frequency of the pulse, a more powerful contraction of the ventricles, and a decrease in the size of the heart if it be dilated. The faradic current does not seem to produce any decided influence on the frequency of the pulse or on the blood pressure, but it apparently has a favourable action on a dilated heart, the area of cardiac dulness decreasing in size after the application of the current. Dr. Franze states that he confirmed these observations by the use of the Roentgen rays, employing the method known as "ortho-diagraphy." He is of opinion that the above results are due to various factors—contraction of the muscular fibres of the myocardium, the direct action of the current on the nervous mechanism of the heart, and a reflex action set up by a stimulation of the sensory nerves of the skin. Dr. Franze further states that the practical results of a course of treatment consisting of a combination of the Nauheim baths with these electrical measures are highly satisfactory and certainly superior to the combination of "baths and exercises" hitherto known as the "Nauheim method." The amount of literature dealing with the mechanical therapeutic measures suitable for the treatment of chronic affections of the heart is now very large. Physicians in this country, however, are by no means unanimous as to the amount of benefit to be obtained by resorting to these methods and further experience of the effects of electric currents in combination with the baths will be necessary before any conclusions can be arrived at in regard to their efficacy.

THE medical officer of health of the Cape Colony states that for the week ending March 4th the condition of the colony as regards plague was as follows. No cases of plague in man or other animal were discovered throughout the colony except at Port Elizabeth and at East London, where plague-infected rodents continued to be found. As regards the Mauritius, a telegram from the Governor received at the Colonial Office on March 24th states that for the week ending March 23rd the number of cases of plague reported was 0. In Brisbane 9 cases of plague were reported during the fortnight ending Feb. 11th and of these cases 4 were fatal.

MANY of our readers will learn with regret that owing to ill-health Mr. F. J. Marshall has been compelled to resign the post of resident medical officer at St. George's Hospital, which he has held for over 30 years. A testimonial is shortly to be presented to Mr. Marshall by his friends at St. George's and elsewhere in token of their regard for himself and of their appreciation of his unvarying kindliness and tact. Subscriptions may be sent to Sir William Bennett, K.C.V.O., honorary treasurer, at 1, Chesterfield-street, Mayfair, W., or to the Dean of the Medical School of St. George's Hospital.

MEDICINE AND THE LAW.

A Twice-convicted Abortionist.

A MAN named Thomas Millerchip, whose name was removed from the Medical Register in 1885 in consequence of a conviction for felony, was sentenced to seven years' penal servitude at the recent assizes at Warwick for performing an illegal operation. The woman herself gave evidence against him and her story was amply corroborated by facts which the prisoner himself did not dispute, such as the enormous fee extorted from her and the fact that he had instructed her to burn his letters to her, both inconsistent with any innocent operation which the most fraudulent quack could pretend to perform. Indeed, the defence seems to have been that he pretended to do more than he actually did. The case in itself did not differ from many others of the same class but for the circumstance that other charges of a similar character which might have been made were referred to before sentence was passed and that a previous conviction for the same offence was recorded against the prisoner which had been punished by a sentence of ten years' penal servitude. It is interesting to note that to criminals of this class previous experience of conviction and punishment does not act as a deterrent but that after emerging from the convict prison they seem always to return to their old courses and frequently find themselves again in the prisoner's dock. The reason for this is indicated in the case of Millerchip by the fee to which reference has been made. The operation which he performed upon his accomplice in the crime, for such, of course, she was, earned for him the sum of £40. The money was "found by a friend" and the prisoner told the wretched woman when she tried to reduce his demand that he sometimes got £70 for assistance of the same kind. He also admitted in the witness-box that he "performed all sorts of operations, mostly upon women." It need hardly be said that a man of this type does not live in affluence but that the temptation to earn without hard work such sums as those named is great. They are also the reward of crimes which it is the interest of those upon whom they are performed to conceal and which may consequently, should all go well, be carried out many times without detection. The manner in which the quack is earning his living may be suspected by the police but evidence sufficient to justify arrest and to secure conviction may be for a long time unobtainable. A crime of a similar nature in that it involves a heavy penalty and yet is perpetrated upon a victim who dares not complain is that of blackmailing and it possesses the same characteristic of large earnings for the successful criminal in proportion to the amount of exertion required of him and the blackmailer also returns to his old ways when he finds himself at liberty In the case of abortion complete secrecy is apt to be rendered impossible by resulting illness and possibly death of the person upon whom the illegal operation is performed, but even then there is always a good chance that her evidence may be buried with her In these circumstances it is desirable that prisoners convicted for a second time for either of these felonies should be treated as habitual offenders determined to persevere in the committal of their crimes and that they should be placed for a long period beyond the possibility of repeating them The frequency of the procurement of abortion is not a matter which can be established by statistics but no doubt in some districts it is considerable and it is a crime aimed against the life of a child as well as dangerous to that of a woman

The Accidental Extinction of Electric Light

In the principal districts of Battersea recently, at about nine o'clock in the evening, the electric light was suddenly extinguished owing to an accident at the generating station The effect of this was, of course not only to plunge streets in darkness but a music hall had to be emptied after the audience had waited in vain for some time and no doubt a large number of people suffered considerable inconvenience and annoyance The danger which this indicates when surgical operations are being performed with the aid of this illuminant alone is considerable In large hospitals it may be possible for the institution to have its own generating plant, to be independent of any error except on the part of its own servants or to minimise the risk of the universal extinction of all the lamps in one portion of the building This, however, is not the case in private hospitals and nursing homes nor can any private house be free from the possibility that in the midst of an operation which may not of itself be of a critical character an element of great danger may be introduced by sudden and unexpected darkness occurring It is a matter which should not be lost sight of upon such occasions, particularly as in private houses, and indeed elsewhere, gas fittings are usually removed where electric light is installed, oil lamps are not kept trimmed, and frequently but few candles are kept in the house at all Extinctions lasting for a few seconds only are by no means uncommon in some districts

Ante natal Injuries

The case referred to under this heading in THE LANCET of March 25th (p 813) is not unique in the records of forensic medicine Several times at home and abroad, has personal injury to the unborn child apparently arising from an accident to the gravid mother come before the law courts for comment or decision In the criminal law it is settled that if a fœtus is wilfully injured, is then born alive and subsequently dies from its prenatal maltreatment an indictment for murder can be sustained In the English civil law, and in at least three of the United States of America, it has been decided that neither the mother nor the child can sue for damages on account of the latter having been born prematurely or otherwise insane in body or mind owing to the wrongful act, sufferance, or default of another There is, however, on record a French decision where very heavy damages were recovered from a negligent medical deliverer by whose aid the plaintiff lost an arm as he journeyed into the world The grounds upon which the English legal view is based are, first, the fœtus is not yet a legal person and hence cannot be wronged, and secondly, the carriers did not know of its presence in their vehicle (e g, a railway carriage or a lift) and so were under no obligation towards it Lastly, such claims would involve the reception of medical evidence too conjectural to be trustworthy and would often necessitate a full discussion as to the theory and fact of "maternal impressions" There is a curious extension to which such actions might lead—a child might sue his own parents for any congenital pathological condition which was probably due to their previous iniquity or carelessness Where the father has been accidentally killed the posthumous child has been allowed, although physically uninjured, to sue for damages and to share in a compensating fund This apparent exception to the general rule is explained by the fact that the claim is in the nature of a right of property or succession, a right which has general application to posthumous children

MEDICINE, ITS PRACTICE AND ITS PUBLIC RELATIONS

CHAPTER VI[1]

THE GRIEVANCES OF THE MEDICAL PROFESSION

(*continued*)

The Evils of Quackery —Quack Advertisements —Prescribing Druggists —The P[illegible] ensing by Medical Assistant[illegible] —Registered Midwives —[illegible] Parson

THE evils of contract practice and the abuse of the gratuitous medical advice and treatment given in charitable institutions have this in common—they may possibly be remedied by reform of the medical profession from within If medical men as a whole were alive to their interests they could set these troubles right at once But other things which weigh hardly on medical men are the various forms of competition which, coming from without can only be removed by some action from without, possibly and to some extent by a change of popular sentiment, but only with certainty by legislation First among these is the competition of quacks Quacks there have always been and quacks there will always be but the immunity enjoyed nowadays by quackery is something a little remarkable, and when its effects on our generation are noted it is impossible not to wonder that no suggestion is ever made, save by medical men that the law should attempt to find a remedy Specific charges have been brought against quacks by their dupes, but almost always it has been found that the charges were not sufficiently susceptible of proof to warrant conviction The licence enjoyed by irregular practitioners of medicine—by persons, that is who possess in the legal sense of the word no licence whatever to practise—is absolutely wonderful It would be ludicrous if it were not so sad Medical electricians, medical hypnotists, medical botanists, and medical masseurs on the one hand, and the votaries of 'safe medicine' bone setters, and the proprietors of patent remedies on the other,—all are ready to treat the community for every ill that flesh is heir to, and all claim to be the depositories of therapeutic secrets which have been denied to the intelligence of men who have made surgery and medicine the study of their lives and who have stood the test of examinations as to their knowledge Surely but very little thought bestowed upon this situation should enable the dullest to see that it is a highly ridiculous one and one that reflects in no creditable manner upon public astuteness and good sense Yet the ignoramus and the product of the highest culture will alike seek the administrations of the quack, and of the two the latter appears sometimes to fall the easier victim The public have to choose the fittest people for their medical advisers The competitors for their suffrages are two—(1) the medical profession, consisting of a body of trained and educated men tested in all the necessary scientific acquirements, and (2) the irregular practitioners, whose credentials are simply their own assertions supported by the corroborative evidence of satisfied patients Which body is more likely to be the really learned one? In every other profession or walk of life the public would at once give their vote in favour of the properly trained body whose proven accomplishments speak for it In every other profession or walk of life self presented testimonials receive the exact attention from the public to which they are entitled, while testimonials from outside are subjected to some scrutiny In medicine alone over such obviously necessary precautions is hesitation to be observed It is easy to see what are the prominent factors which have brought this state of affairs about. Many disorders tend towards recovery; aggravation of these complaints by inappropriate treatment does not necessarily obviate recovery; there are no limits to the imagination of the hypochondriacal and hysterical subject, and there are many diseases, especially diseases of the nervous tracts, the natural course of which is one of remission alternating with exacerbation. The quack fosters every possible delusion in his patients which can arise from these circumstances and reaps a harvest of eulogy, which he immediately prints and disseminates. The bulk of the testimony in favour of unorthodox methods may be obvious and fraudulent concoction, but a certain amount represents the genuine delusion of weak and ignorant patients. Every medical man receives such testimony to his apparent ability but, knowing its worth, he keeps the communication of his patient to himself, whereas the quack blazons it abroad and so, with the favour of the press, is enabled to secure new gulls.

---

[1] [illegible] ed in THE LANCET of [illegible]

For undoubtedly nowadays the quack is strangely favoured by the press. The subject of quacks' advertisements is one upon which public opinion stands much in need of being both formed and stimulated. The discredited quack, when once his methods of doing business have been exposed, secures plenty of reprobation, but the prosperous quack appears able to have his own way with the world. That the general public should be misled by bold advertisement and garbled testimonials is no matter of surprise and, indeed, is too natural to be even a matter of complaint. That a certain amount of quackery should pass muster with the lay press as a form of commercial enterprise can be understood. A newspaper editor or manager may be pardoned if he thinks that the use of his columns to make a nostrum known is a legitimate branch of newspaper business, especially when it is remembered that if he took the opposite view the proprietor of the newspaper might be willing to hear of his resignation. But while this is true with regard to some advertisements it is not true of others, and the disgusting advertisements of many modern quacks ought to be tolerated by no self-respecting editor, manager, or proprietor. Yet no falsehood is too shameless, no promise too palpable a trap, to be refused currency in the advertisement columns of some of the best known journals and it is noteworthy that among the worst offenders in this respect are newspapers and magazines which enjoy with certain classes of the community a high reputation for accuracy and *bona fides*. Regard being had to the lavish expenditure which is bestowed upon advertising some quackeries, it is obvious that those who take toll of the advertisers are participators in the proceeds of this sinister traffic. There have been, it is to be feared, flagrant cases in which an extravagant advertisement has been the price of corrupt silence or even of venal praise on the part of the press. Such practices stand in no need of condemnation. There have been again cases in which, while there has been no such confession of infamy as is implied in a bribe, yet the scale and tenour of the advertisements bore a vicious relation, a high price being asked for a filthy advertisement. Not long since some of the most popular newspapers in the country were accepting regularly the advertisements and money of a crowd of scandalous persons engaged in selling so-called "female remedies." The essence of these advertisements was a promise to pregnant women that certain pills or potions would cause abortion, so that the woman who bought them was either aided in an attempt at crime or else swindled out of her money. By dealing complacently with such customers the editor or the proprietor of a journal, whichever of them may happen to be responsible, makes himself a party to an odious and despicable kind of fraud. The weak, and especially the weak woman, the ailing, and the poor are the chosen victims of the quack. By playing on their fears and taking advantage of their distresses he persuades them to pay exorbitant prices for his worthless goods. Thus does he obtain command of the sums of money which he lavishes in advertisements and those who cultivate his custom must not complain if they are charged with complicity in his misdeeds. It is urgently to be hoped that some attempt will be made soon by legislation to counterbalance the evils of quackery. Medical practitioners are not the only, or even the chief, losers by the mischievous frauds of quacks. The whole country suffers from their evil machinations and it is a thousand pities that no voice but that of the medical profession is ever raised against them. For the opposition of the medical man to the quack, however legitimate, cannot be called disinterested and therefore does not weigh with the public.

While quacks are under discussion the practices of certain persons who are allied to the medical profession, but who, not content with an ancillary position, try to usurp professional work and to encroach upon the province of medicine, should come in for comment. These people cannot be called quacks but, being unqualified, they do the work of qualified persons. Prescribing druggists who give medical advice and opticians who take upon themselves the work of the neurologist are cases in point. The methods of both these classes have long formed a legitimate subject of complaint among medical man and although the harm that is done by their practices may not be very large it certainly shows no tendency to grow less.

The Pharmaceutical Society very properly and strictly forbids its members to prescribe for patients or to take upon themselves the functions of the medical practitioner, but over the counters of scores of dispensing chemists every day and every hour there are given to the public medical advice and medical treatment. There is nothing illegal in the situation, for any unqualified person may give or sell medical advice to anyone else so long as he or she does not pretend to have legal justification to do so. (This must be kept constantly in our minds.) But although no law is broken so long as the dispensing chemist lays no claim to the position of the registered medical practitioner, yet the public are invited to take risks—not always so small as they seem—when they submit their ailments to the diagnosis of the non-qualified man; while an unfortunate separation of interests is created between the medical man and the dispensing chemist. The advisability of the action of the dispensing chemist in prescribing for the maladies of the public is not often defended by anyone. No serious argument can be founded upon the fact that in an emergency the druggist's shop is the natural place of resort. Among his wares will be found undoubtedly the usual stock of restoratives, styptics, bandages, and the like. But the prescribing chemist does not make his harvest out of chance accidents; he has a steady flow of clients who consult him. A defence of counter-prescribing is sometimes attempted on the ground that medical practitioners transgress the boundaries of the dispensing chemist's territory when they dispense their own medicines. And this brings us to a question concerning which there is some difference of opinion among medical men. Is it right, proper, and advisable for medical men in any circumstances to make up and to dispense their own medicines? The answer, of course, is Yes, but even while we say "Yes" we may regret that we cannot answer differently. Undoubtedly it would be advantageous to the medical profession in every way if medical men prescribed their medicines only, leaving the making up of the formulæ to the dispensing chemist. The practitioner would appear to his patient's eye as the dispenser of medical knowledge and as nothing else and the patient would understand that his fees were due to the member of a scientific profession and not to the retailer, however distinctly scientific a branch of business the retailer may be engaged upon.

There have been many suggestions to make it unprofessional for medical men, save in emergencies, to dispense medicines, and quite recently one of the most important branches of the British Medical Association was asked to pass a proposal, to which effect was later to be given in a Parliamentary Bill, that medical men should cease to dispense. The meeting would have nothing to do with the motion because practical members of the association were alive to the actual conditions obtaining in practice. They could see that though the dignity of the medical profession might gain by the divorce of practice from dispensing, the alteration was not feasible. There are many neighbourhoods which are too poor and too sparsely populated to support a dispensing chemist, so that to make it incumbent upon the public to take their prescriptions to the druggist's shop would be impossible. And if it were not impossible in the present state of public knowledge and opinion it would not be wise. Apart from the fact that a poorly paid class of professional men make a small profit by dispensing their own medicines, the public, especially the uneducated public, put faith in a medical adviser who is prepared with a material remedy as well as with spoken precepts. It is a pity that this should be so, but as it is so we cannot ignore the existing sentiment. It is quite easy to see that the medical profession would gain in dignity by leaving dispensing alone but as yet the change cannot be made.

This will be a convenient place to allude to the action of the Pharmaceutical Society which has proceeded recently against members of the medical profession in Scotland for infringement of the Pharmacy Acts, for if the Pharmaceutical Society had succeeded in establishing its whole case something like a forcible division between the practice of medicine and the dispensing of medicine in one part of the United Kingdom would have been accomplished. At the winter meeting of the General Medical Council in 1900 a medical man was summoned to appear before the Council upon the following charge preferred by the Pharmaceutical Society:—

> That he, being a registered medical practitioner, habitually employs as assistants for the sale of drugs and poisons persons who are not qualified to act as chemists or pharmaceutical assistants and thereby causes such persons to commit breaches of the Pharmacy Acts.

It was alleged for the Pharmaceutical Society that practices had arisen in Scotland which broke the law, inasmuch as many medical men owned chemists' and druggists' shops with a surgery attached at which they attended only for two hours or so, the premises being left for the rest of the day in charge of an assistant not qualified under the Pharmacy Acts of 1852 and 1868. The Pharmaceutical Society asked the General Medical Council to regard this situation as constituting "covering," the assistant doing medical or pharmaceutical work under the name of his principal. The General Medical Council considered that the Pharmaceutical Society had made out its case and the Society proceeded to secure more convictions. The defence of the practitioners was that assistants qualified under the Pharmacy Acts could not be obtained in Scotland; that all over the West of Scotland the practice complained of was habitual; that the unqualified assistant received instructions not to sell poisons save under the supervision of his principal; and that the legitimate employment by medical practitioners of dressers and midwives formed a precedent for what was being done. Protests against the view taken by the General Medical Council were addressed to the Council by influential members of the medical profession in Glasgow and possibly as a result of this the Pharmaceutical Society ceased action, but the position taken by the Society was a perfectly logical one—so logical that the prosecutions would have been continued had it not been that the conditions of life made the provisions of the law, when strained in their interpretation, impossible to obey. To compel every medical man to keep a qualified assistant to dispense for him is not possible and the alternative course of employing a dispensing chemist cannot be insisted upon. A dispensing chemist will only be found in a neighbourhood which will support him in the exercise of his calling and until this fact can be got over any attempt to make it compulsory upon a medical man to employ a dispensing chemist must be futile.

Another unqualified rival to the medical man who has lately become active is the prescribing optician, or "optologist," as it has been proposed to call him. The medical man's view of the optician is that he should be an instrument maker and should sell to the public glasses in accordance with the formulæ supplied by the practitioner. He should not consider that a knowledge of optics, whether shallow or profound, fits him to prescribe glasses for the public, because the symptoms of disordered vision require a general medical education for their elucidation. The optician's view of the optician would sometimes appear to be very different. Hear him on himself: "It behoves the optician to know something of anatomy and physiology in general and of the anatomy of the eye and the physiology of vision in particular. He should have some knowledge of neurology and the various nervous ailments which are directly caused by, or dependent upon, eye-strain. He should have some knowledge of ophthalmology in so far as it includes the various diseases of the eye, not for the purposes of treatment but for its prompt recognition in those who apply to him for glasses, in order that intelligent advice may be given the patient to seek medical assistance before the pathological condition has become chronic or incurable." The passage is quoted from a paper in the *Optician and Photographic Trades Review* and the views of the writer are endorsed by the editor of that journal. Such an optician would be more than half a medical man if his attainments would stand the test of examination. Opticians and the attendants in their shops do not necessarily pass any test at all and we may take it for granted that, as a class, they have not any medical knowledge. As far as simple optical principles are concerned the optician is, or ought to be, capable of giving as good an opinion as the medical man. The glasses that he can supply may be quite as correct as those prescribed by the medical man, compensating accurately and perfectly for the defects of the patient's eye; but, unfortunately, in many cases the glasses are none the less unsuitable and should not be worn. Many circumstances have to be taken into consideration of which the optician, even though he have some acquaintance with neurology and ophthalmology, is no judge. The general health of the patient, his avocation, the conditions under which he works, the length of time during which the glasses should be worn, are all points upon which the medical man is better qualified to give an opinion than the optician. The eyes are organs in which faults of shape and alterations of function incidental to advancing life are frequently complicated by physiological defects and pathological changes of a serious character. The knowledge of the qualified medical man should cover the whole range, the knowledge of the optician at the very best covers only a small and comparatively unimportant portion.

The Worshipful Company of Spectaclemakers has recently instituted an examination for opticians which does not include sight-testing in its schedule or provide for a knowledge of the ophthalmoscope, but there is no doubt that the optician to-day does largely test sight and prescribe glasses as well as sell them. His action in so doing is defended by the assertion that there are not enough qualified medical men with ophthalmological knowledge to do the work required by the public. This resembles the reply made by the medical man when he is asked why he performs the office of the dispensing chemist, and it is a correspondingly good reply. It does not, however, make what is wrong right. The remedy for the situation is simple and the General Medical Council is aware of it. The examining bodies must hold special and careful examinations in sight-testing and ophthalmology so that no medical man for the future can obtain a place upon the Medical Register without being able to deal with all ordinary ophthalmological questions.

The gross impositions of the quack, the unfair tactics of the medical aid associations, the immoral use of hospitals, and the ill-instructed rivalry of the druggist and the optician do not complete the troubles of the general practitioner. There are others who should be his assistants and who prove to be his rivals—namely, district nurses, parish nurses, and registered midwives. The mischief done by all these persons is sometimes exaggerated, but their frequent usurpation of medical functions is undoubted. It will be remembered that when the movement which led to the existing Midwives Act was taking shape not a few medical men were seriously perturbed, foreseeing in the registration of midwives the creation of a lower order of general practitioners who would be able, because of an inexpensive training and an incomplete curriculum, to undersell the qualified medical man. Other medical men considered that the registration of midwives must be supported as the measure would secure to the parturient poor safe assistance in their need. There was this noticeable thing about the difference of opinion expressed by the two camps into which the medical profession was divided—they advanced the same claim for their views, viz., solicitude for the parturient poor. The majority of the general practitioners opposed legislation for the registration of midwives because they believed that the midwifery practice of a large proportion of the country would fall to semi-qualified people in whose hands a little knowledge would prove to be the proverbially dangerous thing. Conversely, a system whereby any woman, however ignorant, could attend another woman in childbed without any check being imposed on the possibility that she might not only kill the patient but constitute herself a focus for the spreading of puerperal fever was wrong—obviously and terribly wrong. The Midwives Registration Bill was therefore not so much a Bill for the relief of the sick poor as a Bill for the good of all classes. An Act was required which would protect the poor from the ignorant, dirty, and degraded practices of certain so-called midwives, which would protect the public from the spread of puerperal fever, and which would be able to supply an order of midwifery nurses who would not trespass upon the proper precincts of medical practice—who would not, in fact, practise in contravention of the Medical Acts. The present legislation is an honest attempt to arrive at a middle path between the desiderata. There is no denying that those who argue that the position of medical men under the Medical Acts has been encroached upon by the creation of an order of semi-qualified persons have still a forcible cry, but inasmuch as midwives are a recognised institution, to speak of dispensing with them, as has been done by some of the fiercer upholders of professional privileges, serves no purpose. Midwives must exist and must be made into a clean, reputable, educated class, though their use will be to a certain extent anomalous. The registration of midwives, in so far as it takes the midwifery practice among the lower orders out of the hands of the medical profession and confides it to a semi-qualified class, is, in fact, a retrograde step. For just as the agitation in favour of the registration of midwives was at its height the General Medical Council abolished the unqualified assistant because he was only partially trained, and one of his chief uses was as obstetric adjuvant to his principal. That is to say, that an Act of Parliament now allows women to do what a by-law of the General Medical Council has forbidden men to do. Again, the Act by allowing practically all pre-existent midwives to register has temporarily legalised the "Gamp" against whose ministrations it was aimed. In the future the full benefit of the Act will be felt, but for the present the public and the medical profession alike have but little cause of gratitude.

The same position that is so obvious in the case of midwives exists in the case of district and parish nurses. If these women are unscrupulous in their interpretation of their duties they can supplant the medical man. Undoubtedly, the services of such nurses are of great benefit to the community, but undoubtedly also by preventing medical assistance from being called they have proved now and again a source of danger. As a rule the district and parish nurses do not take medical duties to any great extent upon themselves, but they are apt to breed mischief by preferring to work with certain medical men to the exclusion of other medical men, and for a medical man to be dependent upon the patronage of a nurse is as galling as it is for him to be ousted from practice at the caprice of a nurse. Occasionally a parish nurse is backed up in her wayward behaviour by the parish clergyman and then the medical man, if he is not in favour with the clergyman, is indeed likely to have scant justice dealt to him. Clergymen, especially English country clergymen, are known to have violent medical opinions and prejudices. Many of them, like Sydney Smith, prescribe for their parishioners but they do it without the great humourist's medical education and natural shrewdness. Woe be to the country practitioner who ventures to reprove the prescribing parson!

SIXTY-SIXTH ANNUAL REPORT OF THE REGISTRAR-GENERAL FOR 1903.

I.

IN a leading article in THE LANCET of March 11th, p. 652, we reviewed in some detail what may be termed the administrative part of Sir William Dunbar's report, commenting specially on certain innovations which seemed to us to be of more than ordinary importance.

We now come to notice that portion of the report which shows the distribution of English mortality by cause, age, and locality and contrasts the occurrences of 1903 with those of previous years. The year 1903 was remarkable for its exceptionally favourable mortality, the rate being the lowest recorded in this country since the establishment of civil registration in 1837. In relation to this fact, however, we are reminded of two important agencies which must have largely contributed to the reduction of the death-rate. In the first place, we have not yet emerged from the period in which the lowered birth-rate depresses the recorded mortality. In the second place, the year 1903, like its predecessor, was marked by exceptionally propitious conditions of weather, as well as by unusual freedom from epidemic disease. Bearing these agencies in mind, it is unreasonable to expect that in a country receiving hordes of destitute aliens from all parts of the world the present exceptionally low death-rate will be permanently maintained.

The return of a cycle of hot and dry summers or of very cold winters would inevitably raise the mortality—in the first case, by excessive diarrhœa fatality in the young and, in the second, by undue respiratory mortality in the aged. In either case the tendency would be towards a considerable increase in the general death-rate and this quite independently of the sanitary condition of the country. It is satisfactory to observe that the value of meteorological research, as an essential part of our preventive system, is now officially recognised by those who are competent to judge of its merits. The Registrar-General—who appears to have expressed the obligations of his department to the late Mr. Glaisher on his retirement after 60 years of voluntary service—concurs with Dr. Tatham in his appreciation of the work which Dr. W. N. Shaw of the Meteorological Office has carried on since 1901, in continuation of the labours of his distinguished predecessor. Dr. Shaw's commentary on the conspicuous meteorological occurrences in 1903 occupies a prominent place in this volume and Dr. Tatham commends it to the study of those local observers who are specially interested in matters concerning the public health.

In reviewing the several causes contributing to the unique mortality of 1903 the writer properly cautions us to make due allowance for the defects still observable in the national records of mortality. We learn, in the first place, that of the half million deaths occurring annually in England, fully 10 per cent. are attributed to causes so indefinitely returned as to be practically worthless for statistical purposes, although the bulk of these have been certified by regular practitioners of medicine. In the second place, that in nearly 2 per cent. the causes of death are not certified either by medical men or by coroners; and lastly, that even in cases investigated by coroners the verdict of the coroner's jury often leaves it uncertain whether or not medical evidence had been given at the inquest. To the extent here indicated it is plain that the death records are defective. Nevertheless, with respect to nine-tenths of the deaths occurring in this country we are assured that the cause is medically attested with an accuracy which is steadily increasing year by year.

From the well-known fact that the mortality of most of the diseases that are important in a preventive sense varies enormously according to locality the first step in classification would appear to consist in arranging the various districts of England in groups corresponding as nearly as may be to "town" and "country" respectively. In the present report and in two of its predecessors this has been done, the English registration counties having been grouped so as to show in one list the industrial, and therefore mainly urban, communities and, in the other, the counties that may still be regarded as essentially rural. Inasmuch as the first of these groups contains an aggregate population of about 18,000,000 and the second a population of more than 4,000,000, the deaths therein occurring, being corrected for age differences among the living, afford rates which enable comparison to be made between the mortality of town and country. This method of division has been carried out as regards the mortality from most of the principal diseases and the results would appear to justify the very considerable expenditure of labour involved.

First, then, in respect of the total mortality. We notice a useful table showing the mortality from all causes and at all ages and contrasting "urban" with "rural" England, the crude or uncorrected rates appearing in one column and the corrected rates in another. From this table we learn that after making due allowance for age constitution of the living the mortality in urban England averages 19·2 per 1000, whilst that in rural England does not exceed 14·2. Incidentally it appears that correction *increases* the mortality in the former area by 4 per cent., whilst in the latter correction *reduces* it by 12 per cent.

Another table is given, which is in some respects complementary to that just noticed, because from this table the means are derived for making the corrections referred to. From this table it appears, first, that at the several stages of life from infancy to extreme old age the mortality in 1903 was below the quinquennial average; and secondly, that at every age group, except that from 5 to 15, the death-rate was uniformly the highest in the male sex and this is true alike for the urban and the rural areas. No explanation is offered in the report for the remarkable fact that girls at ages between five years and 15 experience a markedly higher mortality than do boys of the same age; it has, however, been suggested as probable that the approach of puberty is attended with exceptional fatality in the female sex.

The last table shows that, except at very advanced ages, the mortality in childhood is much higher and varies more widely than at other stages of life. It is because the period of infancy is known to be exceptionally susceptible to insanitary conditions that medical officers of health attach supreme importance to mortality at this age as a test of salubrity.

For the present report special tables have been prepared in order to show the mortality among boys and girls respectively from those diseases that chiefly affect young children. In one set of tables are shown the death-rates of infants under one year in terms of registered births and in another set the mortality among boys and girls under five years as a proportion of the number estimated to be living at that age. In all these tables will be found, not only the death-rates for the year 1903, but also the average rates for the preceding five years and, further, the mortality of the urban is contrasted in each case with that of the rural areas. From these tables we find that in England and Wales generally during 1903 the death-rates of infants of both sexes who had not completed their first year was in the low proportion of 132 per 1000 births, against an average rate in the five years immediately preceding of 152 per 1000. Male infants of this age died faster than female infants by 27 per 1000—an excess which corresponds closely with the average. It is perhaps unnecessary to contend that the ill-effects of town life are by no means limited to the earlier ages; nevertheless, for reasons already given, it is with local variations in the loss of life in childhood that sanitarians are especially concerned.

In the year 1903 infantile mortality in urban England exceeded that in rural England by 34 per cent., the excess in the preceding quinquennium having been 31 per cent. Among the several causes of death the most fatal in infancy are wasting diseases, which account for an average mortality of 42 per 1000 births in the country and 45 per 1000 in the town; diarrhœal diseases, for a mortality of 11 and 24 respectively; meningitis and convulsions, for a mortality of 16 and 17; pneumonia, for a mortality of 8 and 13; and bronchitis, for a mortality of 8 and 12. In the case of children under the age of five years we find that in addition to the diseases mainly peculiar to the first year of life diphtheria and scarlet fever now become important factors in the death-rate. The mortality at this age follows the law prevailing among infants in their first year—namely, that the sacrifice of life is by far the heaviest in urban communities. For whilst among boys in the rural districts the rate averaged no more than 44 per 1000 living it amounted in the urban districts to 69 per 1000; among girls the rate in the urban districts was 58 per 1000 but only 36 in the rural.

(To be continued.)

THE TEACHING OF HYGIENE AND TEMPERANCE.

A MEDICAL conference on the Teaching of Hygiene and Temperance was held on March 24th in the Examination Hall, Victoria Embankment, London, under the presidency of Sir William H. Broadbent.

Sir WILLIAM BROADBENT said that the object of the conference was to carry a step further the movement for promoting the teaching of hygiene and temperance in the elementary schools. It was initiated by a memorial signed by nearly 15,000 medical practitioners, which was followed by a largely attended deputation to Lord Londonderry. His lordship expressed sympathy with the objects of the movement but pointed out that the teachers in elementary schools were not as yet qualified to give instruction in hygiene. The training of teachers and the provision of suitable books were therefore the first questions to be considered. Of the necessity for the inclusion of hygiene and temperance in the subjects to be taught in schools there could be no doubt. The State had undertaken the education of the children of the poorer classes and had made attendance at school compulsory. It was therefore the duty of the local educational authorities to make the education given in the schools under their control efficient and to be efficient the education must be such as would fit the children for the places which they would occupy as men and women in the social organisation. It ought to prepare them to take up work by which they might earn their living and also to influence their character for good. If there was one thing more necessary for that end than another it was health and with regard to that the parents of those children were for the most part at once ignorant and careless. The mind of the country just then was much occupied by the question of physical degeneration. Underlying that, and largely responsible for it, was moral deterioration. At the root of both lay ignorance and vice. It was ignorance and vice that should be combated and that could only be done early in life.

Sir VICTOR HORSLEY said that the duty had fallen to his lot of reporting to the meeting the continued success of the action taken by the medical profession in favour of teaching hygiene and temperance in elementary schools. The petition of the profession to the Board of Education had been sent by the distribution committee to the various educational authorities throughout the United Kingdom. Such a large number of bodies from such different parts of the country had returned favourable replies that it was clear that the movement was widely appreciated and that the medical profession had taken a step of practical usefulness in the direction of social amelioration. During the interval the opposition offered by the Board of Education had taken the form of hostile criticism by Sir Michael Foster. Sir Michael Foster attacked in a printed memorandum issued by the Board of Education certain syllabuses which had been in use in some schools. His criticisms were so exaggerated and misleading that an answer had been framed and sent to the Board of Education. The petition committee, after preparing a list of points on which children of various ages might be instructed, was now engaged in framing syllabuses for the training of teachers as well as for the teaching of children. It was, of course, intended that the early training of children should be introduced in association with nature study work and that no new subject should be introduced into the Code. The National Union of Teachers had been misinformed in respect of the object sought to be obtained by the medical profession. It was a question purely of proportionate advantage and the object of the present medical movement was to secure that the subjects of bodily health and vigour and of healthy homes should receive as much attention at least as geography and history. The nation was becoming gradually alive to the duty which it owed to the coming generations but the Board of Education obviously required much more education itself in the direction of hygiene and temperance before the public interests could be adequately served.

Dr. ROBERT JONES made some remarks on the report of the Inter-departmental Committee on Physical Deterioration showing the intimate relationship between ignorance of the laws of health and the use of alcohol and physical deterioration. He pointed out that alcohol had a specially harmful effect upon growing tissues and therefore upon child-life. Alcoholic habits among women were peculiarly deleterious. He urged the necessity of individual effort towards reform.

Sir THOMAS BARLOW said that the change of opinion in regard to the value of alcohol in the treatment of disease which had taken place during the past 50 years had been brought about by increased knowledge coming from a multitude of varied experiences converging along the following lines: first, from the recognition of facts showing the widespread and insidious pathological effects of alcoholism; secondly, observations of the greatly over-estimated value of alcohol in the treatment of disease; and thirdly, the evidence that alcohol was not a necessity as an article of diet. He would be sorry to be prevented using alcohol in conditions of collapse but he considered that it should be used as a temporary aid and that its recurrent use in increasing quantity in acute disease was undesirable. In conclusion he emphasised the importance of recognising that alcohol was one of the luxuries of life and not one of its necessities.

Dr. W. COLLIER, President of the British Medical Association, stated the steps that had been taken by the council of the British Medical Association to promote the teaching of hygiene and temperance. His advice was that reform should be advocated in the most moderate and temperate terms. He pointed out that in regard to alcohol the medical profession was not unanimous on certain points; some said that in no circumstances should alcohol be used even as a luxury while others thought that alcohol had its place in therapeutics. Dr. Collier then proceeded to urge that inasmuch as the medical profession was unanimous on many important points concerning alcohol it was of the greatest importance that those points should be emphasised and that temperate language should be used in regard to the debateable points.

Mr. W. MCADAM ECCLES dwelt on the desirability of all medical students receiving full and sound teaching on the effects of alcohol for they were certain after qualification to be constantly questioned on the subject in all its sociological, physiological, and pathological bearings.

Dr. F. W. MOTT instantly secured the attention of the large audience assembled by stating quite plainly that he was not a total abstainer and that he took wine with his dinner, remarking that wine maketh glad the heart of man. He was glad to understand that Sir Victor Horsley advocated temperance rather than total abstinence because it was more likely that the object of the meeting would be secured by that means. Dr. Mott said he would like to know that there was some possibility of obtaining pure wine that was not adulterated with impure spirit. The evils of alcoholism were increased by the fact that pure wine was being replaced by fuchsine water and adulterated with cream of tartar, and strong raw spirit distilled from vegetable refuse. Dr. Mott quoted the opinion of Liebig that pure wine was a restorative and means of refreshment that was unsurpassed by any product in nature or art. Incidentally the speaker warned the public against thinking that burgundy was a harmlessly light beverage. He next proceeded to show how alcohol acted upon different people in different ways. 20 per cent. of the admissions to the London County Council Asylums were due to drink. Exact knowledge regarding alcohol should be widely circulated among medical men so that care should be exercised in ordering stimulants. He condemned the administration of alcohol in an indiscriminate manner and urged that it should not be ordered as a routine measure, but should only be given when the condition of the pulse indicated necessity for its use.

Professor G. SIMS WOODHEAD welcomed what had fallen from Dr. Mott. They did not wish people to be compelled to be abstainers but they desired to have the opportunity of giving instruction in regard to the effects of alcohol. In that manner there would be a great number of people convinced who would aid in the movement. They had all read in the columns of THE LANCET about the difficulty of procuring pure wine, pure spirit, and pure beer. The demand for highly flavoured and strong beverages was so great that those who had to meet the demand had recourse to means and measures that were quite unjustifiable.

Mr. A. PEARCE GOULD said that if they wanted to make people sober and as wise as Dr. Mott in the matter of alcohol they must instil the necessary information into the minds of the young from very early days.

After Dr. E. SYMES-THOMPSON had said a few words and others had taken part in the discussion the meeting came to an end with a vote of thanks to the Chairman.

Looking Back.

FROM

THE LANCET, *SATURDAY*, March 31, 1827.

MEDICAL HISTORY furnishes abundant examples of the perpetuation of error through prejudice and ignorance, and of the opposition which the most palpable truths have experienced, from men desirous of being regarded as medical philosophers. We may refer, by way of illustration, to the tenacity with which the Brunonian system was so long defended against all the evidence of common sense, and to the reluctance with which it has been forsaken. No system was more plausible at first sight, or better calculated to entrap the unwary: it procured proselytes by its simplicity, and its speciousness deceived those whose time, or want of inclination, did not allow of an immediate scrutiny into its absurdities. At the time of its appearance medical opinion lay prostrate before the chairs of Cullen, Hoffman, and Stahl, or, in other words, medicine was smothered with a scholastic jargon, which even its teachers acknowledged they did not understand. In this state of uncertainty the ingenious hypothesis which reduced diseases into two great classes, and the treatment into an equally simple division, was caught at with avidity, and spread from country to country, until all Europe was desolated with a doctrine which destroyed former errors, by substituting others still more dangerous and absurd. For a time Brunonianism flourished; scarcely a medical school existed, in which it was not publicly taught; and scarcely could a practitioner of eminence be found, who, if he did not vindicate, insensibly fell into its incendiary practice. It was in the full stream of popularity, in France, when Broussais entered his protest against it, and warned his countrymen of the errors they were committing. This was first done about twenty years ago; and although it is difficult to make the voice of one man heard in a multitude, it must afford great satisfaction to that individual, to perceive that his remonstrances served to check the progress of that infatuation, whilst the gradual increase of the opinions he advocated, appears to show that the arguments on which they rested were satisfactory and convincing, that they were, in short, founded in truth.[1]

KING EDWARD'S HOSPITAL FUND FOR LONDON.

THE annual meeting of the General Council of King Edward's Hospital Fund for London was held at Marlborough House on Wednesday, March 29th, H.R.H. the PRINCE OF WALES, President of the Fund, being in the chair, and an influential and representative group of the Council being present.

The minutes of the previous meeting having been read and confirmed,

Lord ROTHSCHILD, the treasurer of the Fund, in presenting the accounts for the year 1904, said that the total amount received by the Fund had been £99,088. £2141 were the amount of the expenses of carrying on the work, which was equal to only £2 3*s.* 2*d.* per cent. on the money received during the year. Of the £99,088, £80,000 were distributed to hospitals and convalescent homes, £13,153 of the available balance represented funds to be held as capital, and £3793 were carried forward. Though this was a very satisfactory condition of affairs he should only be too glad if instead of £99,000 they had £200,000 to deal with. The balance sheet was very satisfactory. On Dec. 31st, [illegible]0, they had investments valued [illegible] names of the trustees and [illegible] ight be of interest to compare [illegible] In 1897 the annual subscrip- [illegible] they amounted to £33,316, an increase of £12,000. They received in 1897 £21,161 on capital account and virtually nothing in 1904, but in 1902 they received £400,000 for capital. In their first year they distributed £56,826, while last year they were able to distribute £80,000. He desired to express his humble testimony of the marvellous work which the members of the executive committee did in carrying out the wishes of the President.

The PRINCE OF WALES having moved the adoption of the account of receipts and expenditure, the motion was carried unanimously.

Sir SAVILE CROSSLEY then read the report of the General Council for the year 1904, which showed the total income of the Fund from general sources to amount to £85,202 14*s.* 5*d.*, there being also received £12 19*s.* 5*d.*, on capital account; and £13,873 3*s.* 6*d.* for the "Additional £14,000 Permanent Income Fund." Gratifying support had been received and the Council was able to carry forward a surplus of about £3000, after distributing £80,000. For this result he especially thanked the voluntary workers of the League of Mercy who had contributed so much towards the increasing success of the Fund. The [illegible] raise the sum (e [illegible] necessary in orde[illegible] President, to take [illegible] an anonymous donor announced in March last, but in a year during which so many other pressing appeals were before the public the task was beyond their powers. By the invitation of His Royal Highness the President, Mr. Edgar Speyer had been added to the General Council and Mr. J. Danvers Power appointed one of the honorary secretaries. Every eligible hospital which applied for a grant was inspected and reported upon and the Council had steadily discouraged any efforts to increase the number of small special hospitals in London. A statistical report dealing with the expenditure of the 16 largest general hospitals had been prepared in order to supply from a central source information as to expenditure and prices. He concluded by alluding briefly to the appointment of Sir Edward's Fry's Committee, whose report had not been received up to Dec. 31st, but has since obtained wide publicity.

The PRINCE OF WALES, in moving the adoption of the report, began by referring to finance. Having reviewed the figures already given he said that the amounts due from small sums, though so valuable in the aggregate, had not shown the same increase as the contributions of large sums and that the Council attached great importance to adding to the number of their subscribers. "I am, however," he added, "especially grateful for the munificence of my ever-generous friend, Lord Mount-Stephen, whose gift of securities to the value of £200,000 was announced after the accounts for 1904 were closed. I also wish to acknowledge with sincere thanks the conditional offer received from Mr. Marshall, which will be equivalent to a gift of £12,000 if his condition is complied with. This condition has reference to our immediate aim, which is to assure for the Fund a permanent income from investments—apart altogether from subscriptions and donations—of £50,000 per annum. With this sum we could practically make sure of being able to distribute £100,000 [illegible] Lord Mount-Stephen's [illegible] of £30,000 of this goal. [illegible]0 of this amount Sir Charles Tennant has given us £3000 to capital, so that only £15,000 are required by July 31st to enable us to accomplish our object. But even then we shall not rest on our oars. The King, in his letter written at the inauguration of the Fund, stated that a sum of from £100,000 to £150,000 were required annually to place the hospitals on a sound financial basis. Since then the population of London has grown, its building area has been enlarged, and hospital requirements have increased. To meet these growing demands I am convinced that our aim must be to provide from the King's Fund an income from all sources which will permit of an annual distribution among the London Hospitals of at least £150,000 a year. This was the original intention of the King when he initiated the Fund and my earnest efforts will be directed towards the fulfilment of that object, which is as near as ever to the heart of the founder. I confidently trust that others will come forward to help us. That their money will be well bestowed they may rest assured and it is most satisfactory to know that the expenses of the Fund are only a little over 2 per cent. on the total amount collected, in spite of the increased work we are now undertaking in different directions." His Royal Highness then alluded to the necessity of the amalgamation of small special hospitals, the present number and position of the various hospitals in London being, to a great extent, the result of chance efforts. From this subject he passed naturally to that of hospital economics, concerning which he said that it was satisfactory to find that in the great majority of cases the efforts of the Fund had been received entirely in the spirit in which they were made. His Royal Highness next made extended allusion to the report of the Medical Schools Committee, consisting of Sir Edward Fry, chairman, the Bishop of Stepney, and Lord Welby. The report, he pointed out, showed that of the 12 hospitals which have medical schools, at least eight contributed from their funds to the support of medical education, while the Committee "do not find that any special considerations have been advanced in justification of the expenditure by the hospitals on the schools." His Royal Highness proposed that the Council of the Fund should begin to act on the report with the first complete year after its publication—that is, in 1906—the hospitals thus having nine months in which to consider their position. "All that we will ask," he said, "is that the whole of the grants from the King's Fund may go to the relief of the sick poor. If a general account is kept for that exclusive purpose, out of which only [illegible] re- [illegible] we [illegible] hile this subject of medical schools remained in doubt, while we were assured that for various reasons it was in the interests [illegible] maintain- [illegible] iew and we [illegible] e report of Sir Edward Fry's Committee we are bound to act upon its recommendations and to reconsider the policy which we have hitherto followed." His Royal Highness considered that such action would be of benefit not only to the hospitals themselves but to medical education as well, and he quoted with approval the statutes of the University of London directing the Senate to secure common courses of instruction for internal medical students in the preliminary and intermediate portion of their studies under appointed or recognised teachers at one or more centres. "I am glad," he said, "to know that the Senate has already put forward a scheme for the establishment of an Institute of Medical Sciences in connexion with the University of London. It is to be hoped that the public will generously support the appeal which has been made for the funds necessary to build and equip such an institute." He concluded an admirable address by congratulating all his colleagues upon the results of the year's work.

---

[1] Extract from the opening words of [illegible] *Examen de la Doctrine* [illegible] dicale, &c. Par J. M. GOUPIL. *Pyretologie Physiologique ou Esprit de la Nouvelle Doctrine* [illegible] p 722. Bailliere. Paris, 1826. [illegible] Edition.)

Mr. JOHN TWEEDY (President of the Royal College of Surgeons of England) personally agreed with His Royal Highness that if this separation were effected not only would it benefit the hospitals as medical charities but he was confident that it would benefit medical education as well. The two parts of medical studies were quite separate. The preliminary science studies and studies such as anatomy and physiology were entirely distinct from the clinical studies. He hoped that, if not within the next year, certainly as soon as practicable, this important separation would be carried out and then in London they would have medical education placed upon a proper footing.

Mr. E. A. CORNWALL (Chairman of the London County Council) having testified to the enormous advantages conferred upon the poor citizens of London by the beneficence of King Edward's Hospital Fund,

The Rev. T. BOWMAN STEPHENSON, D.D., moved a vote of thanks in eloquent terms to the Prince of Wales for presiding.

Sir WILLIAM COLLINS, in seconding the vote of thanks, said that he must say he agreed with Dr. Stephenson in saying that it would be absolutely impossible to over estimate the value of the interest and support of His Royal Highness in the working of the Fund.

The vote having been carried by acclamation, the proceedings terminated with a few words of acknowledgment from the PRINCE OF WALES.

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On an Outbreak of Enteric Fever at the Villages of Eddlesborough and Eaton Bray, by Dr. R. DEANE SWEETING.[1]—Dr. Sweeting gives an account of a small outbreak of enteric fever which occurred last summer in a village which lies between Leighton Buzzard and Dunstable. Part of this village is in Buckinghamshire and is termed Eddlesborough (population 400), the rest of the village, Eaton Bray, with a population of 1000, is in Bedfordshire. Between July 9th and August 19th 33 cases of enteric fever were notified, most of those attacked living in the Eddlesborough portion of the village. Other cases occurred during this period which appear to have been enteric fever although they were not notified as such to the sanitary authority. After August 19th eight additional cases were notified but these in all but one instance were secondary to cases which had already occurred in their families. The case mortality was comparatively low and only three deaths occurred. The cause of the outbreak is shown by Dr. Sweeting to have been the well at Eddlesborough national school. 27 out of the 33 cases notified between July 9th and August 19th were children attending this school. In families which contributed more than one case the earliest attacks were nearly always in school children. The well which supplied the school-house pump with water could not at first be found but eventually it was discovered on digging within two feet of the site of a heap of decomposing excrement from the school privies which had been accumulating there for some weeks before the outbreak of enteric fever and had been removed only after this had begun. It proved to be a shallow well unprotected from surface soakage. Many of the shallow wells in Eddlesborough and Eaton Bray are subject to similar risks of dangerous pollution. The district council of Eaton Bray in 1898 obtained sanction to incur a loan for a public water-supply to the village but had not carried out the work proposed. In view of this recent outbreak and of Dr. Sweeting's report it may be hoped that the Local Government Board, which has already obtained an order of mandamus against this council for its neglect to provide sewerage in Eaton Bray, will now insist as strongly on prompt measures being taken by the local authorities concerned to secure a satisfactory public supply of water for the whole of the village in question.

On the Sanitary Circumstances and Administration of the Borough of Beverley, with Special Reference to the Recent Prevalence of Enteric Fever and Diarrhœa in the Borough, by Dr. REGINALD A. FARRAR.[2]—In the town of Beverley, in the East Riding of Yorkshire (population 13,183), an epidemic of diarrhœa affecting from 200 to 400 persons occurred between April 28th and the end of May, 1904. On the abatement of this epidemic an outbreak of enteric fever followed, the first case of this disease being notified on May 26th and the total number of cases being 32. Only one-third of Beverley is supplied by the Beverley Waterworks Company; the rest obtains water from boreholes sunk to an average depth of from 70 to 80 feet into the chalk beneath the town. Those attacked by the epidemic diarrhœa and enteric fever in nearly all cases were people who lived in houses supplied by the waterworks company or who drank water from this public supply at their places of occupation or elsewhere. The public supply in question is obtained by pumping from a deep well in the chalk 333 feet deep. The chalk in the neighbourhood of the waterworks is much fissured and evidence had been obtained in previous years that contaminating matters deposited on the surface of the ground at considerable distances from the well might find their way into the supply. This was shown in 1885 by the late Dr. David Page and in 1890 Mr. Baldwin Latham demonstrated that lithia placed in a "swallow hole" to the west of the well made its appearance in the well water. Although the waterworks company had taken steps to prevent pollution occurring at the points indicated by Dr. Page and Mr. Baldwin Latham, they had allowed other possible opportunities of contamination to remain. Dr. Farrar points out two places as sources of danger—the farmstead of Bentley New Inn, about three-quarters of a mile south of the waterworks, and a drain situated from three-quarters of a mile to one and a half miles from the waterworks, which receives the sewage of Walkington village. At Bentley New Inn six persons were attacked by acute diarrhœa on March 8th. In connexion with the probable relationship between these cases and the epidemic of diarrhœa which began in Beverley on April 28th Dr. Farrar records that after a comparatively rainless period heavy rainfall amounting to 0·62 of an inch occurred on April 12th and 15th. It would seem that there have now been at least three definite outbreaks of enteric fever which have been attributed to this water-supply. After each outbreak some new source or sources of pollution have been discovered and dealt with and the company can hardly hope that it can obtain entire security for the future by giving its attention to the two places which on this occasion are indicated as dangerous. Filtration of a deep well water is an unusual proceeding but if the present source of supply is to be continued filtration of the water, which Dr. Farrar proposes, seems to be a necessary safeguard. It is true that the character of the water would possibly make it difficult to obtain a satisfactory scum on the surface of the filters but this difficulty, if realised, could no doubt be overcome by suitable means. The precedence of the outbreak of enteric fever by one of acute diarrhœa is a matter of special interest in this epidemic. Those attacked by enteric fever had in most cases suffered from the epidemic of diarrhœa a few weeks before; in fact, the conditions appear to have been closely parallel in this respect to those of outbreaks of enteric fever caused by sewage-polluted shell-fish.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8985 births and 4752 deaths were registered during the week ending March 25th.

---

[1] London, Eyre and Spottiswoode, East Harding-street; Edinburgh, Oliver and Boyd; Dublin, E. Ponsonby. Price 3d.

[2] Ibid., price 4d.

The annual rate of mortality in these towns, which had been 17·1, 17·2, and 15·8 per 1000 in the three preceding weeks, rose again last week to 15·9 per 1000. In London the death-rate was 15·3 per 1000, while it averaged 16·1 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 7·5 in Smethwick and in Wallasey, 7·6 in Handsworth (Staffs.), 8·5 in Walthamstow, 8·7 in Hornsey, 10·0 in Great Yarmouth, 10·4 in Cardiff, and 10·5 in King's Norton and in Rotherham; the highest rates were 22·7 in Southampton, 22·9 in Stockton-on-Tees, 23·0 in Nottingham, 23·8 in Plymouth, 25·8 in Hanley, 27·6 in Portsmouth, and 28·9 in Merthyr Tydfil. The 4752 deaths in these towns last week included 494 which were referred to the principal infectious diseases, against 486, 471, and 430 in the three preceding weeks; of these 494 deaths, 210 resulted from measles, 97 from whooping-cough, 70 from diphtheria, 54 from scarlet fever, 43 from diarrhœa, 17 from "fever" (principally enteric), and three from small-pox. No death from any of these diseases was registered last week in Leyton, Bournemouth, Ipswich, Great Yarmouth, Devonport, or Walsall; while they caused the highest death-rates in Portsmouth, Southampton, Reading, Hanley, Nottingham, Stockton-on-Tees, and Merthyr Tydfil. The greatest proportional mortality from measles occurred in Portsmouth, Southampton, Reading, Nottingham, St. Helens, Warrington, Sheffield, Middlesbrough, Stockton-on-Tees, and Merthyr Tydfil; from scarlet fever in Rochdale and Merthyr Tydfil; from diphtheria in Hanley, Burton-on-Trent, Derby, and Middlesbrough; from whooping-cough in Willesden, Tottenham, Hanley, Preston, Rotherham, and Tynemouth; and from "fever" in West Bromwich. Two fatal cases of small-pox were recorded in London and one in Bury, but none in any other of the 76 large towns. The number of small-pox cases under treatment in the Metropolitan Asylums Hospitals, which had been 15, 16, and 23 at the end of the three preceding weeks, had declined again to 20 at the end of last week; three new cases were admitted during the week, against four, three, and nine in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital on Saturday, March 25th, was 2034, against 2002, 2036, and 2042 on the three preceding Saturdays; 274 new cases were admitted during the week, against 290, 303, and 262 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 353, 361, and 304 in the three preceding weeks, were again 304 last week, and were 79 below the number in the corresponding period of last year. The causes of 44, or 0·9 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Leicester, Nottingham, Bradford, Leeds, Hull, and in 49 other smaller towns; the largest proportions of uncertified deaths were registered in Reading, Burton-on-Trent, Birmingham, Liverpool, Warrington, and Manchester.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 17·4, 18·6, and 18·2 per 1000 in the three preceding weeks, rose again to 18·3 per 1000 during the week ending March 25th, and was 2·4 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 15·4 in Leith and 17·2 in Glasgow, 21·5 in Aberdeen and 26·0 in Greenock. The 615 deaths in these towns last week included 33 which were referred to whooping-cough, 10 to diphtheria, eight to diarrhœa, six to measles, one to scarlet fever, and one to "fever." In all, 59 deaths resulted from these principal infectious diseases last week, against 60, 58, and 52 in the three preceding weeks. These 59 deaths were equal to an annual rate of 1·8 per 1000, which was slightly above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping-cough, which had been 27, 31, and 17 in the three preceding weeks, rose again last week to 33, of which 16 were registered in Glasgow, five in Edinburgh, four in Greenock, two in Dundee, two in Paisley, and two in Perth. The deaths from diphtheria, which had been three, two, and eight in the three preceding weeks, further rose to ten last week and included four in Glasgow, four in Edinburgh, and two in Greenock. The fatal cases of diarrhœa, which had been 17 and 13 in the two preceding weeks, further declined last week to eight, of which five occurred in Glasgow. The deaths from measles, which had been eight, six, and ten in the three preceding weeks, declined again to six last week, and included three in Glasgow and two in Edinburgh. The deaths referred to diseases of the respiratory organs in these towns, which had been 114, 153, and 140 in the three preceding weeks, further declined to 133 last week, and were 32 below the number in the corresponding period of last year. The causes of nine, or 1·5 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 30·7, 25·2, and 23 8 per 1000 in the three preceding weeks, further declined to 22·4 per 1000 during the week ending March 25th. During the past four weeks the death-rate has averaged 25·5 [illegible] 'od being 16·3 per 1000 [illegible] e 163 deaths of persons [illegible] the week under notice [illegible] mber in the preceding week, and included seven which were referred to the principal infectious diseases, against eight, two, and eight in the three preceding weeks; of these, four resulted from measles, one from whooping-cough, one from "fever," and one from diarrhœa, but not any from small-pox scarlet fever, or diphtheria. These seven deaths were equal to an annual rate of 1·0 per 1000, the death-rates last week from the principal infectious diseases being 1·7 in London and 1·9 in Edinburgh. The fatal cases of measles, which had been three, one, and four in the three preceding weeks, were again four last week. The 163 deaths in Dublin last week included 25 of children under one year of age and 49 of persons aged 60 years and upwards; the deaths of infants showed a slight decline while those of elderly persons were in excess of the number in the preceding week. Four inquest cases and three deaths from violence were registered; and 58, or more than a third, of the deaths occurred in public institutions. The causes of nine, or nearly 6 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Staff Surgeon S. T. Reid to the *President*, additional, for three months' hospital course. Surgeons: R. Willan, E. D. Rutherford, M. W. Haydon, and R. H. McGiffin to the *Pembroke*, additional; H. M. Braithwaite, D. G. Addison-Scott, and L. O. Hunt to the *Victory;* H. S. Turner and S. H. Vickery to the *Vivid;* P. D. McI. Campbell, F. G. Wilson, J. McA. Holmes, A. O. Hooper, and E. M. W. Hearn to the *Wildfire;* and A. J. MacDiarmid to the *Pembroke*, all for disposal; W. H. Pope to the *Fire Queen*, for disposal; W. O. B. Smith, F. L. de Verteuil, F. Hernaman-Johnson, and C. R. Worthington to the *Vivid*, to be lent to Plymouth Hospital.

The undermentioned gentlemen have been appointed Dental Surgeons to the Naval Forces and have been appointed for duty at Chatham, Portsmouth, and Plymouth respectively:—Mr. Victor Edwin Mills, Mr. Bannar Harry Martin, and Mr. Albert Harris.

ROYAL ARMY MEDICAL CORPS.

Major E. Eckersley joins at Woolwich for duty. Major C. E. Pollock, Royal Herbert Hospital, Woolwich, has embarked in the transport *Dilwara* for duty at Malta. Major T. Birt has been posted to the Eastern Command for duty. Major J. C. Connor has been appointed for duty in the Southern Command.

ROYAL ARMY MEDICAL CORPS (MILITIA).

Daniel Vere Maxwell Adams to be Lieutenant (dated March 25th, 1905).

INDIAN MEDICAL SERVICE.

Bengal: To be Colonel: Lieutenant-Colonel Henry Kellock McKay, C.I.E. (dated Dec. 3rd, 1904).

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 8th Lancashire: Surgeon-Lieutenant-Colonel A. R. Hopper resigns his commission and is granted the honorary rank of Surgeon-Colonel, with permission to wear the prescribed uniform (dated March 29th, 1905).

Rifle: 2nd (Hertfordshire) Volunteer Battalion the Bedfordshire Regiment: Surgeon-Lieutenant J. B. McBride to be Surgeon-Captain (dated March 25th, 1905). 1st Volunteer Battalion the Royal Welsh Fusiliers: Surgeon-Lieutenant W. F. Byford resigns his commission (dated March 29th, 1905). 4th Middlesex (West London): Surgeon-Lieutenant-Colonel A. Clark (Brigade-Surgeon-Lieutenant-Colonel, Senior Medical Officer, 3rd London Volunteer Infantry Brigade), is granted the honorary rank of Surgeon-Colonel (dated March 14th, 1905). 2nd Volunteer Battalion the Sherwood Foresters (Nottinghamshire and Derbyshire Regiment): Surgeon-Captain W. Moxon resigns his commission and is granted the honorary rank of Surgeon-Major, with permission to wear the prescribed uniform (dated March 29th, 1905). Surgeon-Lieutenant V. J. Greenhough to be Surgeon-Captain (dated March 29th, 1905). 2nd (Westmoreland) Volunteer Battalion the Border Regiment: Surgeon-Major G. W. Brumwell (Brigade-Surgeon-Lieutenant-Colonel, Senior Medical Officer, Lancaster and Border Volunteer Infantry Brigade), to be Surgeon-Lieutenant-Colonel (dated March 25th, 1905). Surgeon-Lieutenant-Colonel G. W. Brumwell (Brigade-Surgeon-Lieutenant-Colonel, Senior Medical Officer, Lancaster and Border Volunteer Infantry Brigade), is granted the honorary rank of Surgeon-Colonel (dated March 25th, 1905). 1st Volunteer Battalion the Northamptonshire Regiment: Charles Humphrey Sedgwick to be Surgeon-Lieutenant (dated March 25th, 1905). 2nd Volunteer Battalion the Queen's Own (Royal West Kent Regiment): Surgeon-Major H. W. Roberts to be Surgeon-Lieutenant-Colonel (dated March 25th, 1905).

DEATHS IN THE SERVICES.

Lieutenant-Colonel Henry William Alexander Mackinnon, D.S.O., A.M.S. (retired), on March 24th, at Weybridge, Surrey, aged 63 years. He joined the Army Medical Service in 1865, became surgeon in 1873, surgeon-major in 1877, brigade-surgeon in 1885, deputy-surgeon-general in 1892, and retired in 1895. He served in the Egyptian war of 1882 and was present at the battle of Tel-el-Kebir, when he was slightly wounded (medal with clasp and the Khedive's star). In the Burmese expedition in 1885-86 he served with the Upper Burma Field Force under Sir George White and was for part of the time principal medical officer (mentioned in despatches, D.S.O., and medal with clasp).

Miss Jane Catherine Shaw Stewart, eldest daughter of Sir Michael Shaw Stewart, sixth Baronet, who died on March 14th at Slinfold, Sussex, at the age of 83 years, was associated with Miss Florence Nightingale in active nursing work in the military hospitals in the Crimea and at the close of the war she was appointed matron-superintendent of Netley Hospital, in which capacity she served till 1868. Miss Shaw Stewart was for some time second Superintendent-General of Her late Majesty's Nurses.

THE ARMY ESTIMATES.

The attention of our readers connected with, or interested in, Army Medical Service matters will very naturally have been drawn to Mr. Arnold-Forster's recent statement on the Army Estimates in the House of Commons. The War Minister was as confident as is his wont as to the importance of his proposals for the reorganisation and reform of the army as a whole and as to the success which would attend and follow upon their adoption. Be this as it may, and it seems clear that he failed to carry conviction to the House on the point, we can only say that uncommonly little can be gathered from what he had to state about the medical services. He repeated his previous announcements that substantial additions had been made to the medical staff, without, however, particularising them, and that a commencement had been made in the construction of the great Military Medical College. It is needless to say that a great deal more than this will have to be done if we are ever to have a medical and sanitary organisation at all adapted to the requirements of modern warfare.

THE WAR IN THE FAR EAST.

The lull at the seat of war still continues but such news as there is from Manchuria does not seem to be of a favourable nature as far as the Russians are concerned. Advices from Harbin state that the Japanese continue slowly to advance. The Russian retreat is described as being still toilsome and dangerous. The commissariat and medical services are completely disorganised. Men who were sick or exhausted from fatigue have had to be abandoned for want of proper transport. Although everything depends now upon the possibility of the success of the Russians at sea, for such an event might alter the whole complexion of the war, little or nothing is really known about the position of the Russian or Japanese fleets.

The Army Council has decided to discontinue the experiment, commenced last November, of providing recruits with artificial teeth and the instructions contained in the War Office letter of the 5th of that month have therefore been cancelled as regards both recruits and trained soldiers.

Correspondence.

"Audi alteram partem."

PROPOSED CONFEDERATION OF THE LONDON MEDICAL SOCIETIES.

To the Editors of THE LANCET.

SIRS,—Attempts have been made from time to time to unite the various London societies representing medical science and practice more closely, so as to form a united Royal Society or Academy of Medicine, in which the existing societies would retain their individuality as sections of the united body.

The present appears a favourable opportunity for again endeavouring to effect this unification and I have gathered from many holding influential positions in the different societies that they would not object to such a confederation being again considered. I have therefore consented to preside at a meeting to be held at the Royal College of Physicians on Monday, April 10th, at 5 P.M., to consider whether it is desirable that the central medical societies of London should unite to form one Royal Society or Academy of Medicine; and, if such union is thought desirable, to take preliminary steps to bring about such federation.

The meeting is open to Fellows and members of all medical societies and it is hoped that there may be a large and representative meeting, as it is desired to gather the opinion of the profession and especially of the junior members of it, as well as that of those who are officially associated with the several societies.

I am, Sirs, yours faithfully,

March 28th, 1905. W. S. CHURCH.

THE TREATMENT OF EMPYEMA.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of March 25th, p. 789, Dr. Samuel West, who speaks with the authority derived from great experience, lays down the law very positively about the surgical treatment of empyema and makes statements with which I, and I expect other surgeons, cannot agree. They do not, in my opinion, tend to improve the treatment of this disease. He says: "In a case where the choice is open the best place to select is just in front of the post-axillary border and on the transverse level of the nipple. It need not be farther down, because directly the pleura is evacuated the diaphragm rises and soon reaches that level. It need not be farther back, because the patient will not lie upon the tube and with the incision in this place he can lie comfortably on the back. If the incision be farther back the patient will turn over on to the opposite side and the drainage will be no better than with the incision in the place I recommend." The directions for the incision are not very accurate. The position of the nipple varies in different individuals and is elevated about one inch by raising the arm. If Dr. West's instructions are followed the opening will sometimes be made in the fourth interspace. But in any case it is, in my opinion, too high and too far forward. It never allows proper drainage when the patient is recumbent, unless he lies on the affected side, and often affords imperfect drainage when he is in the erect posture, because, as a matter of fact, the diaphragm seldom comes into contact with the ribs at so high a level in the side. I have often had to make a posterior incision in cases thus operated on. I believe this position was originally chosen (or rather the sixth or seventh interspace in the axilla) because it was the most easy to get at. I think the best place for [illegible] rib in the scapular line: (1) [illegible] place both when the patient is recumbent and when he is erect; (2) because I do not find that patients object to lying on the back after its performance; and (3) because it seems to me to give by far the best results.

Resection of a piece of rib is not recommended *only* because it provides good drainage, though this is an important object. It allows a free exploration of the cavity and the easy removal of masses of lymph. It also generally prevents the painful gripping of the tube as contraction takes place. No one says that it is always essential, but really Dr. West and some others make too much of this trivial addition to the opening of the chest. It adds practically nothing to the gravity of the operation.

When I hear about shortening the tube in a case of empyema and the tube "preventing the discharge" I feel convinced that too long a tube was employed to begin with. An ideal tube, in my opinion, should be only just long enough not to slip out of the pleural cavity and have one lateral hole only, which should be immediately within the chest wall. It is only in exceptional cases with intricate diverticula that cannot be freely opened up with the finger that long tubes are required. Shortening drainage-tubes in these cases I look upon as a secondary vice induced by the primary one of using too long a one at first. The plan of introducing many inches of drainage-tube is, or ought to be, obsolete. Dr. West talks of two small tubes being as efficacious as one large one; may I recommend him to try two large ones and see if they are not more efficacious still?

Of course, Dr. West knows of Dr. W. Cayley's paper on "[illegible] llowing the Washing Out of the [illegible]" in vol. x. of the Transactions [illegible] ave seen a case of sudden death [illegible] *s propriis oculis*; it was not a pleasant sight. Still, the experience of "many hundred cases" without an accident is large. It makes me hesitate to enter the lists, as it must represent an experience much greater than mine, for I suppose Dr. West will agree that in most cases irrigation is unnecessary. And if unnecessary why add this complication to the dressing if there be even the slightest risk involved in it? After all what a small part of a general empyema can be satisfactorily reached by irrigation unless the cavity be actually filled with the fluid employed for this purpose!

He says: "Estlander's operation is very fatal." This is not my experience if the surgeon does not attempt to do the whole thing at one sitting. That is where the danger comes in. If it be divided into two or three stages, separated by considerable intervals of time, the danger is slight and probably less will have to be done in the end.

Of course, Dr. West will not expect me to agree with him that "the after-treatment of an empyema is better left to [illegible] especially if this involves [illegible] of the drainage-tube, and [illegible]

I am, Sirs, yours faithfully,

March 27th, 1905. RICKMAN J. GODLEE.

SHOCK AND COLLAPSE.

To the Editors of THE LANCET.

SIRS,—Mr. J. P. Lockhart Mummery in his second lecture on Surgical Shock and Collapse[1] suggests the treatment of shock by compressed air wards. In his first lecture he states that "the blood pressure is maintained within a few degrees of the normal range even under extreme variations in outside pressure."[2] It is difficult, therefore, to see in what way the proposed compressed air treatment is to take effect. Mr. Mummery does not draw any distinction between the *absolute* and the *relative* blood pressure. It is the relative blood pressure—that is, the blood pressure compared with the external atmospheric pressure—which is the important factor in the pathology of shock and it is this relative pressure that is recorded in all forms of recording instruments. Alterations in the external atmospheric pressure produce corresponding alterations in the absolute blood pressure but do not materially alter the relative pressure and would not, therefore, be of much value in the treatment of shock. On the other hand, compression of the abdomen—as by the [illegible] matic suit described by Mr. Mummery in which the [illegible] and thorax are not compressed—will raise the relative [illegible] pressure by driving the blood from the dilated splanchnic vessels into the more important areas of the head and chest. It is this form of treatment, therefore, which is of value in cases of shock rather than treatment in compressed air wards [illegible]

WHITE.

ISOLATION HOSPITALS.

To the Editors of THE LANCET.

SIRS,—May I be allowed to reply to Mr. E. D. Marriott's letter of Dec. 24th, 1904, published in THE LANCET of Jan. 7th, 1905, in order to remove a slight misunderstanding on his part? The priority that I claimed was that of utterance of my opinions *in your columns*, as will be made evident, I think, by collating my letter (published in your issue of Dec. 17th, 1904, p. 1737) with your leading article of August 27th, 1904, p. 624, on which my letter commented; and I consider that my claim is justified. Your phrase implied that Mr. Marriott was the first person to express disapprobation of isolation hospitals in THE LANCET and I ventured to correct this in my own behalf. Further, if Mr. Marriott will look back to my original letter in THE LANCET of June 13th, 1896, he will see that I had *not* "contented myself with a letter in THE LANCET" but had been for some time contesting with the local board of guardians (St. George's, Hanover-square) and its medical officer of health (the late Dr. W. H. Corfield) and his sanitary inspector the right of these officials to remove scarlet fever patients to the fever hospitals indiscriminately, even contrarily to the wish of the relatives and of the medical man in attendance. I appealed to the Local Government Board and obtained a decision in my favour. The purport of my letter was to publish an account of this dispute with the result; and I also stated my experience of the effects of the infectious diseases hospitals of the Metropolitan Asylums Board. I am glad to hear that Mr. Marriott has been engaged with the question as long as he has been and that he is still carrying on the fight; but his previous writings on the subject were quite unknown to me.

I am, Sirs, yours faithfully,

F. LUCAS BENHAM, M.D. Lond.

Exeter, South Australia, Feb. 10th, 1905.

THE MEDICAL MAN AS EXPERT WITNESS.

To the Editors of THE LANCET.

SIRS,—*Apropos* to Dr. W. B. Ransom's interesting paper on the medical man as an expert witness, in THE LANCET of March 4th, p. 591, will you kindly allow me to point out that the medical witness is frequently not an expert at all; that he is called in by, and employed by, the prosecution; is expected to assist the police in order to secure a convic[illegible] cannot be reconstituted, it is [illegible] his decision? It must be admi[illegible] ngerous state of affairs; the prisoner or accused or suspected person ought always to be represented at these investigations by another medical man, practitioner, or expert in the first instance, before the body is buried, if it is a case of death, or the symptoms or condition which are supposed to indicate guilt on the part of the accused have passed off. I recollect a case where a woman was declared to have died from the effects of an illegal operation. Fortunately, the friends were able to employ another practitioner who completed the post-mortem examination by opening the skull and so ascertained that the patient had died from apoplexy. The Grimsby starvation case is another instance in point. Here the symptoms of death from starvation of the prisoner's wife were conspicuously absent and yet the man was convicted and got 20 years' penal servitude, some portion of which he had served when he was rescued by a memorial to the Home Secretary setting forth the facts. It is the same when men have been accused of rape and the decision of the court depends upon the existence or non-existence or recent rupture of the hymen. The medical witness has here a delicate and difficult investigation about which the most eminent jurists have differed. The ordinary practitioner, unused to such cases, cannot, of course, be expected to give evidence of any value and yet his testimony is held sufficient to convict, and as he is the only one present in the first instance there can be no appeal against his decision. It is the same when the fate of the accused depends upon the results of a chemical analysis. If an analyst had been employed on behalf of Mrs. Maybrick he might have found that there was not enough arsenic in the tissues to have caused death or that the amount discovered would readily be accounted for by the medicinal doses which Mr. Maybrick was in the habit of taking. Again, if an expert in handwriting had checked the conclusions arrived at by Mr. Guirin in the Adolf Beck case the latter half of Mr. Guirin's report would not have been suppressed and Mr. Beck would not have been convicted. Again, if an independent expert had examined the horsehair and blood said to have been found upon Mr. Edalji's trousers he might have found that there was no blood or horsehair or that the presence of both might have been sufficiently accounted for without assuming the guilt of the accused.

In short, Sirs, it is impossible to get at the truth without full discussion and hearing of both sides. The medical man is quite right to do the best he can for the person who employs him; he is bound to do for him what he would do for himself if he were able. The prosecution are straining every nerve and resorting to every device in order to secure a conviction quite irrespective of the innocence or guilt of the accused and if the medical expert does not do his very best to save his client he is unworthy of his position and of no use at all. Medicine is not an exact science and never will be and the man who comes into court to expound scientific truth to the laity is expounding something that does not exist. As to Crown referees they would be simply glorified expert witnesses and as we should have no control over them they would be much more dangerous than anything we have at present.

I am, Sirs, yours faithfully,
C. BELL TAYLOR, M.D. Edin.
Nottingham, March 25th, 1905.

THE GOUTY DIATHESIS.

To the Editors of THE LANCET.

SIRS,—Will you kindly allow me to make some remarks on Dr. D. Chalmers Watson's letter which is, in my opinion, rather aggressive? Your correspondent does not deny the fact that the knowledge of the physiology and pathology of the thyroid gland is very incomplete, and, on the other hand, he says that "one is perhaps justified in hesitating to attach much scientific value to Dr. Arany's pronouncement on the results of his clinical experience regarding a relation between gout and the thyroid gland." I daresay my professional and literary reputation is not unknown to members of the profession of both European and American countries, and I do not think that anybody will doubt in the honesty and seriousness of the reports of my observations as well as in my being up to date as far as the literature of gout and thyroid gland is concerned.

In saying that in the series of my cases of gout I did not observe in a single case any symptoms which could have related to changes in the thyroid gland I only referred to symptoms of well-known affections of the thyroid gland, as it goes without saying, we cannot do the same with patients as we do with rats—viz., examine their thyroid gland by means of the knife. As I am going abroad in the course of next week I shall not be able to reply to Dr. Watson's future objections (if there should be any) and therefore consider this my final remark on the subject.

I am, Sirs, yours faithfully,
Royal Societies Club, March 18th, 1905. S. A. ARANY.

URINOSCOPY.

To the Editors of THE LANCET.

SIRS,—There are numerous medicine men throughout South Wales and amongst these, I believe, some qualified chemists "who read the water." These men assume the power of being able to diagnose any and every disease by simply holding up a bottleful of the patient's urine between them and the light and looking through. This is indeed a wonderful power of discernment and a very substantial asset to the fortunate possessor, far exceeding, from a financial standpoint, any medical diploma or degree. On the other hand, considering the few diseases that can be diagnosed from the urine alone I consider the assumption as almost a complete deception of the public or as supplying goods under false pretences and should be investigated by the police with a view to punishment.—I am, Sirs, yours faithfully,

March 25th, 1905. WELSHMAN.

THE MEDICAL CONTROL OF SCHOOLS AT NEW YORK.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

(Concluded from p. 824.)

THE figures already published indicate that the number of children excluded from school was so high as seriously to interfere with the work of education. This was due more especially to the great prevalence of acute disease of the eye and of pediculosis. Yet the board of health insisted that, even at the risk of depopulating the schools, it was its duty to protect children who were clean from any risk of contagion. Nevertheless, the stringency of such regulations was ultimately relaxed. The method now adopted is to send away at once any child who is found with live pediculi. But when the child is under treatment the mere presence of nits while only in the embryonic stage is no longer considered as practically rendering the case contagious. The children under treatment may then attend class but only on condition that their hair is shampooed with kerosene and olive oil. Then later the hair must be thoroughly washed and dried. After this the hair is rubbed with hot vinegar so as to dissolve the shells of the nits and these must be brushed away with a hard brush. A pamphlet with full, clear explanations to this effect is given to each child. At first, however, this relaxation of the rule did not suffice. A great number of the children excluded had no homes where they could be privately but efficiently treated. The public dispensaries where children who did not possess suitable homes could be treated were not sufficiently numerous. Consequently many children remained indefinitely away from school because they could not get attendance, not even the commencement of a proper treatment. At this juncture the Nurses' Settlement came to the assistance of the department of health and sent a nurse to see whether something could not be done i order to enable the children to return to school.

For some six weeks experiments were made and in th year 1902 it was decided that a regular nursing syster should be established to look after the children wh attend the primary schools. Eight nurses were appointe for children frequenting the schools of what is legall denominated the borough of Manhattan. The missio of these nurses is to attend to children who, thoug suffering from communicable complaints, are nevertheles admitted to the schools. This permission is granted notably i cases of pediculosis, conjunctivitis, and some forms of diseas of the skin. Such relaxation of the rules came into operation on Jan. 1st, 1903. The eight school nurses were place under the direction of one supervising nurse. The school were divided into groups and each nurse had to atten several schools. The supervising nurse was held responsible; she was expected to visit each of her nurses while the were at their work and this at least once a week. The schoo nurses had to keep a record of all the cases which the treated. When a child was excluded from school and di not return on the day appointed the nurse had to call at th child's home and to ascertain the cause of the delay. Th nurse had also to instruct the parents as to the proper wa of cleansing the children's heads. Definite and precise rule are given to the nurses for the treatment of pediculosis, conjunctivitis, ringworm, impetigo, favus, molluscum contagiosum, scabies, &c. It is the school inspector wh remits to the nurse the details of each case and th nurse acts accordingly but these nurses are not allowe to deal with *cases of trachoma. The department* o education supplies to the schools, on demand from th principals of the schools, whatever is necessary for the treatment by the nurses of the children It very soon became evident that the system now instituted involved such an amount of work that the number of school nurses was quite insufficient Before six weeks had elapsed the staff of nurses had to be doubled and after an increase from eight to 16 nurses there was a further augmentation to 19 nurses The probabilities are that by this time a still larger number is employed In any case, the figures given of the work done during the year 1903 show that the position of school nurse is no sinecure The number of cases treated for pediculosis was 156,886 for contagious diseases of the eye 106,257, for eczema 3379, for ringworm 8498 for scabies 335 and for miscellaneous complaints, including favus, impetigo, and molluscum contagiosum, 10 438 The total number of cases treated is set down at 285,793 Then 12 891 visits were paid to the homes of the pupils, 11,098 visits to the schools, and 293 miscellaneous visits, making in all 24,282 visits

It soon became evident that these school nurses were destined to render great service apart from the mere treatment of the afflicted children All kinds of indirect advantages began to accrue from the action of the nurses who, by the force of circumstances, were at times playing the part of missionaries of civilisation To get a child from a slum dwelling and make him attend an excellent school is already a great step forward Much of the good this would produce is, however, undone when the child returns home But now it is not only the child that is sent to school, it is the trained nurse that comes from the school to the child's home Thus some very practical phases of education are brought to the child's home for the instruction of the parents and family The action of the school nurses first helped greatly to reduce the number of children excluded from school, thus the care taken of the health of the children no longer seriously interfered with the education of the coming generation But what is especially beneficent are the visits the nurses pay to the homes of the children, for there they are able to discover and to cause to be removed insanitary conditions and sources of infection from which not only the children but entire families suffered This gave the nurses splendid opportunities for spreading in a practical and very effective manner a better knowledge of sanitation and the laws of health Then, again, the children who formerly were excluded on account of ill health not infrequently became permanent truants Now a good watch is kept to see first that they are properly treated and secondly that they return to school as soon as it is safe for them to do so

When once it was decided to admit into the schools a large number of pupils while still under treatment it was necessary to devise a method of watching them very closely Therefore—and this happened during the course of March, 1904—what is known as the "card index system" was introduced Each class room has a card and on it is inscribed the name of each pupil attending that class though suffering from a communicable disease For this purpose a code number is employed so as not to divulge the complaints of the children It is from this class card, if no separate and special instruction is given, that the nurse learns who are the pupils she has to treat and what are their complaints Practice has demonstrated that each child must be taken separately and told individually what he must do If several children who have the same complaint are grouped together and then told they do not pay sufficient attention, are not duly impressed, and very generally fail to carry out the instructions The class card also enables the school inspectors to follow out what is being done For instance, if to a child's name is affixed the indication "under treatment" the school inspector forthwith proceeds to assure himself that there has been proper treatment and, if not at once excludes the child There has been some difficulty about the code numbers as the children are sharp enough to find out their meaning, even though numbers that had no meaning were occasionally thrown in to try to put them off the scent and two or three different numbers were used to signify pediculosis

By means of this card system and the school nurses the diseases for which the child is at once and rigorously excluded till completely cured were reduced to the following diphtheria scarlet fever, measles, varicella, pertussis, mumps, and acute coryza As an example of the effect of the modifications described, which is due in the main to the work done by the school nurses, the following figures are given. During the previous three months ending on Dec 3rd, 1903, the exclusions from school amounted to. measles, 18 cases, diphtheria, 140, scarlet fever, 13, pertussis, 61, mumps, 9, trachoma, 12,647, pediculosis, 8994, chicken pox, 172, contagious diseases of the skin, 661, and mis- [illegible] the [illegible] of [illegible] let fever, 13, pertussis, 61, measles, 18, mumps, 9, and chicken-pox, 172, or a total of only 400 Consequently the new system would have prevented the interruption during the short period of three months of the studies of 24,138 children It cannot now be said that the medical inspection of the schools seriously interferes with education

In New York, as elsewhere, there is no lack of parents who are more anxious to make use of their children than to secure for them a good education Consequently when it was found that a child excluded from school for some slight complaint would not be readmitted unless under proper medical treatment the parents neglected to obtain such treatment To meet this difficulty the school authorities had to consult the district attorney and as a result the following notice was issued —

> Any parent who refuses to put its child under proper medical treatment that it may return to school is violating the compulsory educational law and is guilty of a misdemeanour punishable by a fine

This was supported by the magistracy, for in a test case the parent was fined $10

The figures given above have shown the alarming prevalence of diseases of the eye and this fact naturally did not escape the attention of the health authorities Early in the year 1902 five ophthalmic surgeons were appointed to investigate the matter and after examining a considerable number of children they declared that 17 per cent were suffering more or less from trachoma Thereupon the school inspectors were sent to the New York Eye and Ear Dispensary so as to gain fuller experience in detecting this disease Each inspector was required to spend two hours a day at this dispensary for about a fortnight But as the cases in the schools were by these means more promptly discovered the number of children excluded increased so rapidly that they soon created an unmanageable crowd at the hospitals and dispensaries In several cases the medical staff was so overwhelmed that some of the surgeons did not stamp the cards which the children brought Consequently such children could not be readmitted to school because they had nothing to show to prove that they were under treatment Of course, complaints arose and ultimately the department of health had to fit up a special eye hospital and dispensary for the school children At this hospital for trachoma 4337 school children were treated by operation during the year 1903 The number treated without operation was 11,599 Thus there were altogether 15,936 patients The number of visits for subsequent treatment amounted to 129 830 and the total number of consultations or "treatments" (to use the phraseology of the report) was 145,766 Apart from this 3121 children were examined but it was found that they were not suffering from trachoma Of course, more trained nurses were required for this hospital and they were obtained from the training school at Blackwell Island It is a very significant fact that when a proper surveillance rendered it impossible to continue to neglect the children it was found that the hospitals and dispensaries of New York no longer sufficed for the work that had to be done Con [illegible] cities will see [illegible] n the mere [illegible] oper care is [illegible] of medical inspection is introduced into the schools of the great towns in the United Kingdom it is probable that in many instances it will also be found necessary that the education and health authorities should create some special hospitals for the children But this is not all Bacteriological laboratories will be needed on a much more extensive scale than at present exists in this country [illegible] bacteriological laboratory They were all examined and in 10 376 cases nothing was detected, 318 showed some doubtful bacilli, and in 757 cases the Klebs-Löffler bacilli were detected. Have the large boroughs of England the necessary organisation to make a similar experiment?

In regard to vaccination, two inspectors visit the schools so that every child is offered vaccination and any child not successfully vaccinated within five years of school life must be revaccinated. Thus during the year 1903 the number of school children vaccinated amounted to 26,168. Yet it is very rare that primary vaccination is performed at the schools, for the children are not admitted unless they have a vaccination certificate. Thus the school period is the period of revaccination. It is estimated that 90 per cent. of the vaccinations made at school are successful. As for the usefulness of such measures, this was conclusively demonstrated during the severe epidemic of small-pox in 1901 and 1902. Though 10 per cent. of the cases that occurred at New York were among children of the school age—that is to say, from the age of six to 16 years—not one single child attending the public schools contracted the disease.

At the conclusion of his admirable report, the assistant chief medical inspector, Dr. John J. Cronin, says that the medical inspection as at present organised is attaining the end which it has in view but that much remains to be done which appertains to other administrative departments and other social forces or conditions. For instance, the care taken of the children's outer garments leaves much to be desired. In many cases the class-rooms are not properly ventilated, the light is sometimes insufficient, and there is some overcrowding. Personally, while in New York I had only time to visit two of these schools and both were on the East side. One was an old building for which considerable ingenuity had to be displayed to adapt it to educational purposes. Nevertheless, the proper unilateral light had been secured in the class-rooms. The other school was a huge structure only recently built and expressly for school purposes. Here I was much gratified to see that powerful engines were at work, so that revolving fans might provide the entire premises with the air needed. Mechanical ventilation alone is trustworthy and its introduction in this new and model primary school constituted an example which, it is to be hoped, other nations will not delay in following.

The report goes on to recommend the establishment of baths in the public schools, the examination of the eyes and the correction of errors of refraction, and mentions that of 981 children whose eyesight was examined about 30 per cent. suffered in this manner. Then it is urged that the children's teeth should also be examined and properly treated. Greater care should be taken for the correction of any deformity of the locomotive apparatus. All nervous diseases should be excluded from the class-rooms. Hypertrophied tonsils and adenoid vegetations should be removed. But, above all, what is needed is the abolition of the dilapidated and overcrowded tenements where so many children are forced to live under health-destroying conditions. In dealing with this phase the reporter concludes with the following words:—

> I certainly do feel hopeful, however, that while all the good that we would wish for may not be realised in the present generation of school children, for the reason that they, too, are powerless to change their [illegible] stowed upon them now will so dissatisfy [illegible]ndition and surroundings that they will [illegible] for no power can gainsay public indigna[illegible] [illegible]tter homes for the bringing up of their children and the latent pride that is in their breasts will become active and exhibit itself in the better hygienic care of their children. Then as far as bodily cleanliness and disease are concerned there will be no lo[illegible] l equal and the purpose of [illegible] he department of health of [illegible]

These are not the words of a Utopian, a poet, or a public agitator, but of a medical officer written in the fulfilment of his duty as a public official. If we compare the medical inspection of the children attending the New York schools and the very successful feeding of all the children attending the schools in Paris with what prevails at home, it will have to be acknowledged that in Great Britain, and especially in London, there remains still much to be done.

MANCHESTER.

(From our own Correspondent.)

The Royal Infirmary.

At the monthly meeting of the board of management of the Manchester Royal Infirmary held recently the question of the speedy completion of the new infirmary and the giving up of the Piccadilly site to the corporation came up for consideration. A scheme had been proposed by two gentlemen for providing a temporary hospital on a site near Stanley-grove, to contain 300 beds, so as to hand over the present infirmary sooner and to obtain an earlier payment from the corporation. A subcommittee had gone over this scheme and came to the conclusion that it would involve a loss of over £20,000 and that it was not advisable to adopt it. There is a natural wish, not to say an impatient desire, both on the part of the corporation and the infirmary board, to have the whole transaction finished as soon as possible. Nowadays we rebel against space and time and endeavour to annihilate both, but a building to accommodate many hundreds must not be run up after the fashion of the jerry builders who build to sell and not to last. One prominent member of the corporation seemed to consider the building operations as dilatory, and this was emphasised in a letter from the town clerk to the board, suggesting that the latter did not appear "to give any consideration to the needs of the corporation in respect to the building operations which they had in contemplation." In answer to this a statement was sent showing that the architects were of opinion that the new infirmary would be completed in three and a half years or at the outside in four years from the putting in of the foundations. As regards the use to which the Piccadilly site should be put a new suggestion is now exciting attention. It may be remembered that a favourite scheme was that an art gallery and free library should replace the present building. But it has been growing in the minds of the members of the Manchester Exchange that, notwithstanding the fact that the place in which they congregate is said to be the largest room in Europe, they are fearfully overcrowded, that the ventilation is bad, or rather insufficient, and that the air they breathe is pestiferous, and, moreover, that the site does not allow of its being enlarged. Hence the idea has been broached that a new exchange should be built on the Piccadilly site. A good deal may be said in favour of this scheme. The site is central and commanding and its purchase would relieve the corporation and the ratepayers of a portion of their heavy financial burden. It is to be hoped that mutual forbearance will be shown by the corporation and the infirmary board and that the building of the new infirmary will progress without loss of time.

"Presence of Mind."

Much is heard to-day about degeneracy, both mental and physical, so that it is refreshing to meet with instances of courage and agility, more especially when occurring in those so seriously handicapped as the boys of a deaf and dumb school. Two or three weeks ago a teacher at the Cross Deaf and Dumb School, Preston, awoke about two in the morning and found that the boys' schoolroom on the ground floor was on fire. He roused the inmates and telephoned for the fire-brigade. Some of the smaller boys were very naturally frightened but "there was no panic and the teachers were able to keep them well in hand" till a way of escape was provided. The school engineer got through a window and to the ground by means of sheets tied together and one boy climbed down by a water spout. Ladders were brought and the boys got down one by one. In one of the dormitories there were a number of little fellows who had to climb through windows and along the roof to another room before they could descend. Very plucky little fellows they must be. "Finally, the boys were mustered, counted, and found to be all safe." The fire-brigade got the fire under but considerable damage was done. At 6 A.M. the boys were busy printing postcards to send to their friends informing them that they were safe and would be in school at 9 o'clock. This little narrative tells enough to show that there was coolness in danger of a kind to take hold of the imagination, that discipline must have been good, and that many of the smaller boys showed both courage and activity in getting through windows and along a roof. There could have been no spoken directions, none but those given by fingers or gesture, or by lip-reading; no excited shouting but a silent escape in the dead of night. This speaks well for the school except perhaps as to the arrangements for escape in case of fire. It would seem that they might be improved.

Extension at Oldham Infirmary.

The Victoria commemoration extension of the Oldham Infirmary was opened on March 24th. It provides accommodation for 43 patients and eight servants and contains operating theatres, x ray and photographic rooms, electric lifts and lighting arrangements, also an out-patient department. It has cost over £20,000, of which about £1500 are still unpaid. In formally handing over the new extension to the chairman of the governors the speaker said that "the new extension had brought up the old part of the infirmary to modern lines."

greed that

ication of

pulmonary tuberculosis has been a failure. The latter gentleman reports that only 50 notifications were received in four years in the Knutsford, Winsford, Middlewich, and Bucklow districts, though there had been 139 deaths from pulmonary tuberculosis and there were probably 200 surviving cases.

March 28th.

LEEDS.

(FROM OUR OWN CORRESPONDENT.)

The General Infirmary.

IN moving the adoption of the annual report and balance-sheet of the infirmary, the treasurer, Mr. Charles Lupton, after referring to the amount of work done during the year 1904, took occasion to discuss at some length certain points in hospital management to which attention had been especially directed since the speech of the Prince of Wales at the annual meeting of King Edward's Hospital Fund. Referring to the excellent work inaugurated by Mr. Danvers Power at the National Hospital for the Paralysed and Epileptic, London, Mr. Lupton was able to assure the subscribers that nearly all the methods which had been recently adopted by that hospital with such a marked lessening of expenditure had been the methods adopted in Leeds for many years. Economy was practised wherever it was thought possible without a loss of efficiency. Mr. Lupton called attention to the fallacies underlying apparently the simplest of figures. A correspondent in the *Times* had published in tabular form some figures bearing on the finance of some of the London and provincial hospitals. In the column headed "cost per bed" the Leeds Infirmary stood at the sum of £73, while another large hospital in a northern city stood at £55. As a matter of fact, the method adopted in different hospitals of estimating the "cost per bed" varied so much as largely to discount the value of such comparisons. An examination of the figures quoted showed that 6139 in-patients and 40,113 out-patients were attended to at the Leeds Infirmary at a cost of £28,514, while in the other hospital 3144 in-patients and 20,441 out-patients were attended to at a cost of £14,939. If for purposes of comparison the figures of the second hospital were doubled throughout it would be seen that the two institutions were on pretty much the same scale as regards expenses in relation to the number of patients treated. There were many circumstances which caused the expenses of different hospitals to vary. Geographically Leeds was highly favoured, for coal and gas were cheap and the water-supply was excellent. The hospital was opened in 1868, and though its age was therefore as nothing compared with the age of many of the London hospitals they were beginning to feel the increasing cost of a building past its first youth. In repairs to the structure, in bringing sanitary appliances up to date, in painting, and in washing the expense during the last three years had been very great. Mr. Lupton referred to the discussion which had lately taken place as to the advisability of making charges to the patients for special articles of diet, such as sugar and tea or butter, and discussed the plan of charging 3*d.* a bottle for medicine which had been strongly advocated by the chairman of the London Hospital. Personally he was quite against this system, feeling sure that it would encourage an impression on the part of the patients that in paying even this small charge they were discharging all obligation to the infirmary; for, he remarked, it was no use informing a patient that the advice was worth two or three guineas and then charging 3*d.* for the bottle of medicine. In Leeds, therefore, when it was decided that a patient was a suitable person to receive hospital aid no charge was ever made but many patients made voluntary gifts and these were always gratefully received.

Smoke Abatement.

Some experiments have lately been carried out by the corporation at the electricity generating works. The principle involved is the use of a mechanical forced draught by means of one of Matthews and Yates's "Cyclone" blowers. The experiments are said to have been very satisfactory. The mention of "smoke abatement" is apt to raise a cynical smile on the countenance of the dweller in Leeds. He has heard of this before and he thinks of his white curtains at home and of the condition of his linen after a few hours' wear. It is to be hoped, however, that the corporation may succeed in lessening the production of smoke in its own departments, for this will strengthen its hands in insisting that others shall make similar efforts.

Proposed Sanatorium for the West Riding.

In spite of some opposition it is believed that the scheme for the provision of a sanatorium for the West Riding will be carried out. Provisionally a site has been secured in the parish of Chapel-le-Dale, at about an equal distance from Ribblehead and Ingleton. In freedom from smoke, in beauty of scenery, in excellence of soil, and in accessibility the site selected leaves little to be desired.

March 28th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Cardiff Port Sanitary Authority.

THE annual report of the medical officer of health of the Cardiff port sanitary authority (Dr. Edward Walford) records a large amount of useful work carried out during 1904. Every vessel, foreign or coastwise, is boarded by an officer of the authority immediately upon entering the outer basin of the dock. The master or person in charge of the ship is required to fill up a form stating what port he has come from, the number of his crew and passengers, whether there has been any sickness of an infectious nature during the voyage or at the time of arrival among either crew or passengers, and the nature and the result of sickness of any kind. Hitherto this information has been obtained verbally but it is obviously an advantage to have it in writing. The six inspectors, acting under the medical officer of health, inspected 8171 vessels during 1904 and found defects in 1408. In 1903 they found 1228 vessels defective among 8072 inspected. During last year 79 vessels entered the port from places which were either infected or suspected of being infected with plague. The medical officer of health examined 2111 persons on board these ships and the names and addresses of all those who left the ships were taken and forwarded to their destination. No cases of plague or of suspected plague were brought into the port. More than 3000 rats were destroyed either by sulphurous acid gas or after being caught in traps. The Cardiff and county public health laboratory continues to assist the authority in examining samples of drinking water from vessels. In 1903 samples were examined from 66 ships and 46, or 70 per cent., were reported to be impure. In 1904, of the 87 samples examined only 56, or 64 per cent., were said to be impure.

Swansea Port Sanitary Authority.

Mr. Ebenezer Davies, the medical officer of health of the Swansea port sanitary authority, in his annual report states that 1481 defects were found in the 5286 ships inspected at Swansea during 1904. Of the total number of British ships inspected 9·4 per cent. were found with one or more defects which required to be remedied; in the case of foreign vessels this percentage was 30.

Illegitimacy in the Rhondda Valleys.

All those who have studied the housing question in the colliery districts of South Wales have deplored the custom which exists to a very large extent of taking single men as lodgers in the small dwelling houses. One of the worst features of this custom is the amount of illegitimacy which results. In the Rhondda Valleys in 1903 there were 115 illegitimate births, a number which is equal to 13·3 per 1000 of the unmarried and widowed women living in the district between the ages of 15 and 45 years, taking the census figures of 1901 as prevailing in 1903. In the whole of England and Wales during the same year the proportion was 8·4 per 1000. A par

the Cardiff assizes hel

under the Criminal L

young girl who gave

catarrh, induce typhoid fever or that simple gastro-intestinal disturbances predispose to it is not supported by these investigations. The percentage of deaths in 20,738 cases in 92 regiments was 7·61. The fact is dwelt on with much emphasis that typhoid organisms are found in the urine of about one-fourth of all cases and that the frequency with which it is voided, its comparative inoffensiveness, its easy dissemination, and the relatively great number of organisms present, render infected urine the most dangerous excretion of the typhoid fever patient. One immediate result of this investigation was the adoption of a system of disposal of excreta in fixed camps by means of a trough containing milk of lime and emptied by an odourless system.

The Panama Canal Mismanagement.

The report of Dr. Charles A. L. Reed, who was sent to the canal zone by the Secretary of War for the purpose of examining the operations of the Commission, shows that the chief sanitary officer, Colonel Gorgas, is so hampered in his work by the Commission as to imperil seriously the success of the enterprise. The medical profession was desirous of having Colonel Gorgas a member of the Commission in order that he might have a controlling influence upon the sanitary branch of the service. The President, however, advised that there be "one head of the medical department" and he was appointed to that position in the belief that he would have more time to devote to these duties. The result has been that in his subordinate position he has been constantly under the narrow policy adopted by the Commission and has been unable to fulfil his mission. The medical staff can carry on no work not sanctioned by the Commission and to obtain its approval requires a delay that prevents the effective use of measures. To this delay is attributed the appearance of yellow fever at Panama. Dr. Reed mentions many instances of the failure of the medical department to accomplish the reforms that it projected and concludes that very much has been done in the way of sanitation in exceedingly unfavourable circumstances; that much remains to be done which cannot be effected unless better facilities are afforded; and that very much more ought to be done and would have been done if the facilities had been properly furnished.

March 18th.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Instances of Municipal Misgovernment: Proposal for Provincial Sanitary Reform.

FROM time to time I have to record the incapacity and the apathy of municipal bodies and the intervention of the Government to obtain better administration. The last defaulter is the Kumbakonam municipality in the Madras Presidency. This town is, for its population, one of the richest in the province and also one of the most important. Amongst other serious defects, neglect of sanitation, vaccination, and vital statistics figure prominently. Instead of dealing thoroughly with such a recalcitrant body—it has already had cautions—the Government merely threatens it with a paid chairman in place of an elected one. Here, surely, is a direction in which the sanitary improvement of the mofussil towns of India might be more under direct supervision and control—viz., by appointing an officer of the Indian Medical Service as chairman who could insist that such powers as were possessed by local bodies should be utilised and that the sanitary administration of the towns should be kept up to a reasonable standard. Where one municipality is disfranchised or admonished there are dozens in which all administration, and especially sanitary control, is neglected. Unless there is someone at the head of these provincial town councils to keep them up to the mark they are in danger of drifting on in an apathetic way until their administration becomes a scandal and sanitary neglect often goes on for years until some financial irregularity brings the municipality to serious notice. As a measure of sanitary reform for India the appointment of such an officer as chairman (and perhaps one officer might act for two, or even three, towns) would be a step of great value and might be made the basis of the special sanitary service for India.

The Nursing Services in the Bombay Presidency.

A scheme has been proposed for the amalgamation of the nursing services of the Bombay Presidency by forming a Western India Training Association under the control of the local government, the nurses to be trained at one and the same school and the candidates to sit at one and the same examination. The nurses would be sent from one hospital to another. The scheme does not find favour with the nurses themselves but the present system is unsatisfactory because the nurses work under different associations, each of which has its own nursing staff. The whole question is under the consideration of a special committee.

The Plague Epidemic.

The latest plague returns show again a rise after the moderate set-back of the past fortnight. For the week ending Feb. 25th 29,465 deaths were recorded throughout India, as against 27,837 for the previous seven days. The outbreak at Aden is serious. A few isolated cases occurred last November but in December 207 cases with 162 deaths were reported. In January 423 cases and 326 deaths occurred and in February the mortality has been at the rate of about 250 deaths per week, but the returns for the last week show that some improvement has begun. Considering the small population the death-rate is very high. The United Provinces return 12,213 deaths, as against 10,869 for the previous week; the Punjab, 6940, as against 6976; Bengal, 4914, against 4761; Bombay districts, 2400, against 2514; Hyderabad, 602, against 319; Rajputana, 459, against 553; Central Provinces, 403, against 424; Mysore State, 274, against 295; Madras districts, 258, against 261; Bombay city, 735, against 618; and Calcutta, 130, against 88. It is a very curious fact that the figures for Rangoon and Poona and Karachi are not included in the usual list. The disease is rapidly increasing in Calcutta and Bombay city; in the latter the death-rate is over 115 per 1000 per annum.

The Special Plague Department of Calcutta.

There is a proposal to abolish this department, chiefly on the score of expense. I hear, however, that it has been for the past two years very economically worked and that in addition to plague operations a considerable amount of other sanitary work has been given to it. It is argued that because Bombay reduced its expenditure by handing over the administration of plague to its health department Calcutta might be able to do the same. The two cases are not parallel. Calcutta has never spent much on plague while at Bombay the expenditure has been enormous. Moreover, in Calcutta the plague department has been instrumental in effecting many very valuable sanitary reforms in regard to which no attempt had been made by the health department. It is very questionable, therefore, whether the proposal will be carried through.

It is understood that Major Cleveland, I.M.S., who was deputed from Poona as medical attendant to the Amir in October last, has been obliged to arrange to return to India owing to private affairs.

March 10th.

NEW ZEALAND.

(FROM OUR OWN CORRESPONDENT.)

Charge of Manslaughter against a Medical Man.

THE grand jury brought in a "no bill" in the case of Dr. Collins who had been committed on a charge of manslaughter because of his treatment of a case in the Auckland Hospital. Judge Edwards, in his charge, seemed to indicate that had he been the magistrate of the lower court he would not have committed the medical man. This case has undoubtedly occupied the attention of the public and the profession throughout New Zealand in a manner rarely seen. For some time past the relations between Dr. Collins (late medical superintendent of the Auckland Hospital) and the profession in that city have been of a very strained nature. The result was that practically all the best surgeons left the honorary staff and the vacancies were filled by men some of whom had had but a limited surgical experience. In consequence of certain allegations the Government directed that Dr. D. Macgregor, the inspector-general of hospitals, should hold an inquiry but before his report was made public a Royal Commission was appointed to inquire into the alleged mismanagement and as a result of the commissioners' report an action for manslaughter was brought against Dr. Collins. From the evidence, which is set out verbatim in the last number of the *New Zealand Medical Journal*, it would appear that a steward of one of the coasting boats was taken to the Auckland Hospital. He complained of pain over the left lower part of the abdomen. Dr. Collins diagnosed appendicitis and opened over that organ, only to find that it was quite normal. Dr. Neill, one of the honorary staff, swore that he urged Dr. Collins to make a median incision because in his opinion it could not be appendicitis. A median incision was made and the bowel was examined but no rupture was found. Two pieces of fæcal matter were found and, according to the evidence, Dr. Collins made two incisions in the bowel and removed these fæcal masses, which were of "about the size of a walnut." The whole charge of "accelerating the death of the patient" was based upon these incisions. The operation was then proceeded with and two ulcers in the upper part of the stomach were said to have been discovered and stitched up. Further examination revealed a ruptured duodenal ulcer which was stitched up. The operation occupied about one and a half hours. The patient died soon after his removal from the table. At the departmental inquiry held by Dr. Macgregor four of the honorary staff swore that they saw the ulcers in the stomach. An order for exhumation was issued by the Colonial Secretary, when it was found that as a matter of fact the stomach was quite healthy and that the only lesion other than those made by the surgeon was the ruptured ulcer in the duodenum. It is a matter for great regret that the whole thing had not been thrashed out in the Medical Association, although at the same time it is quite evident that some power should be given to the inspector-general to step in and to check indiscriminate and unskilful operative work if such obtains in any hospital. Doubtless it might be awkward if all surgeons had to stand the same searchlight examination which Dr. Collins underwent and although the profession generally has suffered discredit there can be no doubt that the inquiry and the trial have made for the better management of our hospitals.

Sanatorium for Consumption.

His Excellency the Governor, accompanied by Lady Plunket, the Hon. Sir J. G. Ward (Minister of Public Health), and Dr. J. M. Mason, chief health officer of the colony, recently inspected the Te Waihato Sanatorium for the Treatment of Consumption. The institution is capable of [illegible] and is really one of the best of [illegible]. It is situated on a range of hills in one of the most salubrious parts of the North Island. There are 1000 acres of land much of which is covered with native bush. The shelters are most artistic and of the latest pattern. The whole place is lighted by the electric light. Already some very good results have been obtained. It is managed entirely by the Government and there is a limited accommodation for paying patients.

Patent Medicines.

The new regulations issued by the health department, requiring that all "patent medicines" must have the formulæ set out on the label, have caused quite a commotion amongst those who live on the credulity of the public. In deference to the pressure brought to bear by the newspapers and quacks generally the regulations have been modified. It is now required that the formulæ should be deposited with the Minister of Public Health and that all mixtures containing poison must have the words "this contains poison" set out in gothic type on the label. There is no doubt that this is a very decided step in the right direction.

Private Hospitals.

[illegible] all private hospitals to be lic[illegible] have already eliminated ma[illegible] Another year or so and New Zealand may fairly claim that the *rich* as well as the *poor* will have equal chances of recovery.

Feb. 10th.

PRESENTATION TO A MEDICAL MAN.—At a meeting held at the Church Missionary Society Hall, Bristol, on March 23rd, under the presidency of Colonel H. B. Savile, C.B., Dr. J. H. Loch was presented with a roll-top desk, a chair, a typewriter, and an illuminated album containing the names of 300 subscribers. The album bore the inscription, "Presented to Deputy-Surgeon-General J. H. Loch, M.D. (Indian Medical Service, retired) in grateful recognition of his earnest and self-denying labours for the past 12 years as honorary lay secretary of the Bristol Church Missionary Association."

Obituary.

MAURICE GRIFFITH EVANS, M.D. ABERD., L.R.C.P. LOND., M.R.C.S. ENG., L.S.A.

Dr. Maurice Evans of The Mount, Caerphilly, Glamorganshire, who died recently in his seventy-third year, was the son of a former vicar of Llangolman, Pembrokeshire. After serving an apprenticeship to his uncle the late Dr. Phillips of Newcastle-Emlyn he became a student at Guy's Hospital and took the diplomas of M.R.C.S. Eng. and L.S.A. in 1853. In 1859 he graduated as M.D. at King's College, Aberdeen, and was admitted a Licentiate of the Royal College of Physicians of London in 1872. Some 45 years ago he commenced to practise at Narberth in Pembrokeshire where he took a leading part in all public and philanthropic movements and especially interested himself in the work of the Royal Society for the Prevention of Cruelty to Animals. While at Narberth he contributed two articles to THE LANCET; one in 1859 on cases of retention of urine due to retroversion of the uterus and one in 1869 on nicotine poisoning. About 30 years ago he removed from Narberth to Cardiff where he had an extensive practice. In 1881 and 1882 he was president of the Cardiff Medical Society. About ten years ago he retired from professional work and went to live at Caerphilly. He was a life-long abstainer and took much interest in Church work, being a lay elector for the Llandaff Diocesan Conference. At the funeral, which took place on March 20th, there was a large attendance, including many ministers of religion of various denominations, medical men, magistrates, and others. The procession was headed by the officials and members of the Eisteddfod committee and each wore a white bow in respect of the useful and long association of the deceased with the annual festival. The service, which was fully choral, was conducted by the Rev. Connop L. Price, rector of Caerphilly, the Rev. J. Williams, vicar of Trallong, and the Rev. M. L. Evans of Aldershot. At the graveside a very impressive Welsh service was conducted by the Rev. D. Griffiths of Brynmawr and the rector of Caerphilly, and preceding the benediction the well-known hymn, "O Fryniau Caersalem," &c., was sung by the assembly to the tune of "Crugybar."

AUGUSTUS DAVID MARTIN TALBOTT, M.R.C.S. ENG., L.S.A.

Mr. A. D. M. Talbott died suddenly at his residence, 14, Richmond Hill, Clifton, Bristol, on March 23rd, in his seventy-fourth year. The deceased, who received his medical education at St. George's Hospital, became qualified as M.R.C.S. Eng., L.S.A., in 1852 and 1853 respectively. Mr. Talbott had been for many years in practice at Clifton and continued his professional work until within a few days of his death. He had been for 40 years the honorary local secretary of the Royal Humane Society and took the greatest interest in the work of the society; he had also been very energetic in introducing the teaching of swimming in the Bristol elementary schools. Mr. Talbott will be much missed and sincerely regretted in Clifton and Bristol. He leaves a widow but no children.

Medical News.

VICTORIA UNIVERSITY OF MANCHESTER.—At examinations held in the Faculty of Medicine in March the following candidates were successful:—

FINAL EXAMINATION.

[illegible] Harris Jones, A. W. [illegible] t, J. B. [illegible] I, Hey, [illegible] James [illegible] d J. S. Young.

* With honours.

SECOND EXAMINATION.

A. Anatomy and Physiology.—J. W. Bride, G. W. Bury, Harold [illegible] Frederick Hall, Frank Coppock, D. J. [illegible] Alice Hartley, Robert [illegible] Rodger, Oberdorfer, George [illegible] J. V. Elsie M. Royle, [illegible]

Steward, T. W. Todd, F. D. Walker, G. B. Warburton, and Henry Whitehead.

B. Materia Medica and Pharmacy.—T. E. Dickinson, W. P. Moffet, and Samuel Rawlinson.

WE have been asked to remind our readers that the dinner to be given on Wednesday, April 5th, to Mr. W. Johnson Smith by the medical staff of the Seamen's Hospital Society will take place at the Trocadéro Restaurant at 7.30 P.M. Dinner tickets can be obtained at the offices of the Seamen's Hospital Society, 13A, Cockspur-street, London, S.W.

RUSSIA INVITES FOREIGN MEDICAL AID.—According to the *Novoe Vremya*, the large number of medical men called up for military service has made numerous vacancies in public institutions, &c., which it has been found impossible to fill up from amongst Russian citizens and the Medical Council has had to consider the question of admitting medical practitioners with foreign diplomas to practise in Russia. The decision is in favour of the measure, the chief reason for which is the need for dealing with a possible invasion of cholera. Foreign medical men desiring to practise in Russia should be well acquainted with the Russian language and should be able to show that they have already served in some medical establishment for at least two years.

NATIONAL ASSOCIATION FOR THE PREVENTION OF CONSUMPTION.—The sixth annual general meeting of the National Association for the Prevention of Consumption was held on March 23rd, at 20, Hanover-square, London, W. The chairman, Lord Derby, in moving the adoption of the report, said that he hoped that the association and its work would be brought prominently before the City at a meeting to be held at the Mansion House on May 17th. Provision should be made, he thought, for advanced cases of pulmonary tuberculosis and for cases beyond recovery. Dr. Nathan Raw, who seconded the motion, said that treatment of advanced cases in sanatoriums had caused scepticism as to the utility of these institutions in the minds of some people but it should be remembered that the sanatorium could only be expected to confer benefits on those patients in the early stages of the disease who were also otherwise suitable cases for treatment. Dr. L. A. Weatherly supported the motion which was carried. Sir William Broadbent proposed—

> That in the interest of the public health it is necessary that consumption and tuberculous disease generally in the metropolis should be dealt with in a comprehensive manner and that this will be done most efficiently by the Metropolitan Asylums Board constituting itself the sanatorium authority for consumption in London.

Dr. C. Theodore Williams seconded the motion which was adopted. On the motion of Mr. Malcolm Morris, seconded by Dr. H. Mackenzie, the auditors and the honorary secretary (Dr. J. J. Perkins) were re-elected and the meeting closed with the usual courtesies to the chairman.

CENTRAL MIDWIVES BOARD.—The members of the Central Midwives Board met on March 23rd at 6, Suffolk-street, Pall Mall, S.W., Dr. F. H. Champneys being in the chair. The re-election of Dr. Champneys as the representative of the Royal College of Physicians of London, of Dr. J. Ward Cousins as the representative of the Royal College of Surgeons of England, and of Mr. E. Parker Young as the representative of the Society of Apothecaries was notified. It was announced that Dr. W. R. Dakin had been elected as the representative of the Incorporated Midwives Institute. The Board was informed by the clerk of the county council of the West Riding of a resolution of the county council suggesting the reduction of the certificate fee to 2*s.* 6*d.* or some less sum. This was discussed and it was agreed that no action should be taken in the matter. The Board then considered a letter from Dr. J. McLiesh asking the Board to reconsider its decision not to recognise the certificate of the Belfast Union Maternity Hospital as an approved qualification under Section 2 of the Midwives Act. The Board decided that no action should be taken in the matter. A letter was read from the President of the Liverpool Ladies Charity and Lying-in Hospital asking the Board to constitute Liverpool an examination centre and a letter was also read from Dr. H. Briggs, professor of midwifery in the University of Liverpool, forwarding a memorial to the same effect signed by certain medical officers of health and other members of the medical profession in Liverpool and the adjoining districts. This request was not acceded to by the Board. The Board then considered a letter from Mr. E. Sergeant, medical officer of health of Lancashire. By the rules of the Board "a midwife must decline to attend alone and must advise that a registered medical practitioner be sent for ...... in the case of lying-in women ...... upon the occurrence of" a "rise of temperature above 100·4° F. with quickening of the pulse for more than 24 hours," and it appeared, according to the inspectors of Mr. Sergeant, that some midwives were ignorant of the use of the clinical thermometer. The opinion of the Board was that the women should be instructed and their attention called to the rules. It was announced that the total number of midwives on the roll amounted to 18,231 The Board adjourned to April 27th.

DONATIONS AND BEQUESTS.—Under the will of Mr. Richard Cadbury the following hospitals will receive legacies—viz., the Temperance Hospital, London, £10,000; Birmingham General Hospital, £5000; Birmingham Eye Hospital, £5000; Birmingham Ear and Throat Hospital, £2500; and Birmingham Orthopædic Hospital, £2500.—Mr. Alexander Fry has by his will left £500 to Charing Cross Hospital and £500 to the Royal Hospital for Incurables.—By the will of the Rev. Thomas Hulme the sum of nearly £16,000 will be divided between the Sheffield Royal Hospital and the Sheffield Royal Infirmary.—The Royal Halifax Infirmary will benefit by the sum of £1000 under the will of Mr. Edward Crossley.—Under the will of Miss C. Squire, Gloucester-terrace, Hyde Park, the Westminster General Dispensary receives a legacy of £200 free of duty.

UNIVERSITY OF LONDON.—A meeting of the Faculty of Medicine was held at the University, South Kensington, on March 24th. Dr. J. K. Fowler, the Dean, occupied the chair and there were 63 members present. Dr. Lauriston E. Shaw was elected to represent the faculty on the Senate for four years from May next in place of Sir E. Cooper Perry, whose period of office will come to an end on that date. A vote of thanks was given to Sir Cooper Perry for his services as Senator during the past four years. The Dean announced that Mr. Alfred Beit had promised to increase his donation towards the fund for building and endowing a University Institute of Medical Sciences from £5000 to £25,000. A vote of thanks to Mr. Beit was carried by acclamation. The faculty approved of a proposal that on the occasion of the return visit of British physicians and surgeons to Paris in May next, the Dean of the Faculty of Medicine should take some special steps to do honour to the memory of Pasteur. It was resolved that in the opinion of the faculty it was advisable that pass lists of Bachelors' degrees should be issued in alphabetical order and without classification. It was resolved that it was desirable that members of boards of studies associated with the Faculty of Medicine should retire in accordance with some definite plan and a committee was appointed to prepare a plan and to submit it for the approval of the faculty.—The council of King's College has elected Dr. Peter Thompson as Professor of Anatomy and Professor Arthur Dendy, D.Sc., of the South African College, Cape Town, as Professor of Zoology.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC.—The annual general meeting of the members of the Medical Graduates' College and Polyclinic was held at the College, 22, Chenies-street, London, W.C., on March 25th, Dr. Theodore Williams being in the chair. In proposing the adoption of the annual report of the council the chairman said that it showed that the Polyclinic was progressing, on the whole, very favourably. The institution was increasing its sphere of usefulness and the number of members was greater than before. The attendance at the lectures, demonstrations, and practical classes had not in any way lessened. He drew the attention of the members of the profession to the fact that the examination of specimens of sputum and analyses of different kinds were undertaken at the laboratory of the Polyclinic. Some of the very best teachers in the medical profession lectured at the Polyclinic and the council and the members of the institution were much obliged to them. He congratulated the members on the fact that the balance-sheet showed that the Polyclinic had been able to pay its way and to save a little money. Mr. James Berry, in seconding the adoption of the report, said that that was the first year since the College had been founded in which the expenditure and the income had balanced. As treasurer he had to admit that the financial condition was satisfactory but still he wanted more money. He praised the medical superintendent, Captain A. E. H. Pinch, for the successful financial result. The motion for the adoption of the report was carried unanimously.

Mr. Edward Roberts of Oakfield, Hale, one of the honorary surgeons to the Manchester Royal Eye Hospital, has been appointed High Sheriff for the ensuing year for his native county of Cardigan.

A LECTURE entitled, "The Bible in the Light of Modern Science," will be delivered by Mr. William Woods Smyth, at the Stafford Rooms, Edgware-road, London, W., on Friday next, April 7th. The chair will be taken by Sir William Broadbent at 5 o'clock.

THE GARCIA CENTENARY.—The *Musical Times* for April contains a very full and most interesting account of the Garcia Centenary, with illustrations. There are a portrait of Manuel Vicente Garcia, the father of Manuel Garcia, the illustrious maestro whose 100th birthday occurred so recently, a reproduction of the well-known portrait by Chalon of Maria Garcia (Madame Malibran), a reproduction of a daguerreotype taken in 1848 of Jenny Lind, Garcia's most famous pupil, a reproduction of a sketch by Doyle of Hallé and Garcia playing chess, Manuel Garcia as he was 50 years back at the time of the invention of the laryngoscope, and lastly, a special reproduction on plate paper of the recently painted portrait by Sargent. A short account of Garcia's career is given as also a full description of the centenary celebrations. Among the other articles we are glad to see one calling attention to the beauties of Bach's choral preludes. Why is it that these wonderful compositions are so seldom played?

THE STANDARDISATION OF DRUGS.—Messrs. Evans, Gadd, and Co., of Exeter, in the most recent edition of their price list for medical men, have included a short introductory essay on the Standardisation of Drugs, explaining their methods. When the chief active ingredient of a drug is known and can be readily isolated an estimation of it gives approximately the value of the drug, but in the case of some of the most important drugs the cause of their undoubted activity cannot be traced to any definite constituent and the drug can only be standardised by physiological tests. For example, ergot is tested as to its ecbolic efficiency by experiments on pregnant guinea-pigs and the cardiac tonics, digitalis, strophanthus, and squill, can only be effectively tested by their action on the living heart of the frog, and Messrs. Evans, Gadd, and Co. state that the preparations which they offer have been so tried.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Pharmacy Bill.

FOUR Members—Mr. BATTY LANGLEY, Mr. ALEXANDER CROSS, Mr. JAMES BAILEY, and Sir MARK STEWART—have given notice to move the rejection of the Pharmacy Bill when it comes on for second reading.

HOUSE OF COMMONS.

WEDNESDAY, MARCH 22ND.

The Home Office and the Vaccination Act.

Mr. WEIR asked the Secret[illegible]
whether in view of the fact [illegible]
[illegible]
orm of a return
on the subject

The Prime Minister and the Conscientious Objector.

Mr WEIR asked the First Lord of the Treasury whether he was [illegible]
I never heard
that any objection felt by candidates to being vaccinated themselves would constitute conscientious objection. The conscientious objection is to the vaccination of their children.

The Physical Condition of School Children.

[illegible]
Education was powerless to provide for the feeding of children in the elementary schools. When the Board was charged with being slack in carrying out the recommendations of this committee he must remind the House that the report was issued only last July and that throughout the autumn he had been inquiring of persons with a practical [illegible]
n which
be dealt
meals for
ildren to
have their meals regularly at school must have disastrous results What it was necessary to get at was the extent of the evil and the proper remedy It would not be fair to attack the department for negligence in a matter of such pathetic importance when the essential facts were not known and when a false step must have such serious consequences.

THURSDAY, MARCH 23RD.

Vaccination Prosecution.

Mr. PHILIP STANHOPE asked the Home Secretary whether his attention had been called to the case of Jabez Wilson Harrison of Burgh le Marsh, Lincolnshire, who had already suffered two months' imprisonment impc [illegible] by the magistrates of Spilsby and
Boston and who was [illegible] of
a month inf [illegible]
consequence [illegible]
and the refus [illegible]
tion; and wl [illegible]
attention of [illegible]
and intentio [illegible]
objectors—M [illegible]
[illegible] which I gave to the honourable member for [illegible]
is in each case one for the discretion of the magistrates, with which I have no power to interfere" I regret that I do not feel justified in advising any remission of the sentence.

The Viewing of Bodies at Inquests.

Mr. KEIR HARDIE asked the Home Secretary whether his attention had been called to the remarks of Mr. Coroner Graham,
of Consett, anent th [illegible] practice
of compelling juries t [illegible] ts were
being held; and wheth [illegible] putting
an end to this practi [illegible] tention
had not been called t [illegible] read a
newspaper report of th [illegible] as good
enough to send me [illegible] ble the
practice to be disconti [illegible] fer the
honourable Member to the answers given by my predecessor on Feb. 22nd and March 29th, 1900, to the effect that there was no such decided preponderance of expert opinion in favour of any definite change in the law as would afford a reason for proposing legislation of the kind suggested.

[illegible]

trains and begging scraps from the men; and, if so, what immediate steps he proposed to suggest in order that the needs of these children might be so attended to that they might be in a position to profit by the instruction offered to them.—Sir WILLIAM ANSON answered: I have read the evidence to which the honourable Member refers but I think he will agree with me that in so serious a matter statements made to a
a lady, who communicated them
erioration would hardly furnish an
action. I may add that I have
of the practice referred to and my
informants have added that it by no means follows that the children thus supplied cannot be fed at home.—Dr. MACNAMARA: Having regard to the fact that this lady is an official of the department, may I ask whether the honourable gentleman has any doubt as to the truth of her statements?—Sir WILLIAM ANSON replied: No, sir, none whatever.

Dr. MACNAMARA further asked whe
agraph
lorsing
Trainir
sirable that the preparation and cooking
of meals for underfed school children ought to be regarded as one of the charges incident to school management; and whether he was in a position to assist the putting of this recommendation into practical effect.—Sir WILLIAM ANSON said: My inquiries on this subject have led me to believe that the wisdom of preparing and cooking meals on the school premises as a mode of dealing with those cases in which children need to be provided with food elsewhere than at home is seriously open to question.

MONDAY, MARCH 27TH.

The Physical Condition of School Children.

Sir JOHN GORST asked the Secretary to the Board of Education

Royal Commission on Physical Training and the Departmental Committee on Physical Deterioration will be laid before the new committee referred to. The terms of reference sufficiently indicate the character of the fresh evidence which that committee is intended to take and the consideration of the report of the Committee on Physical Deterioration will only be suspended in respect of the matters included under that reference. I cannot say whether a report will be made before the end of the session.

Sir JOHN GORST also asked the Secretary to the Board of Education whether the Board of Education would address a circular to local education authorities advising them to instruct the managers and teachers of public elementary schools to refer the case of children attending their schools, hungry and destitute and unable from affliction to profit by the instruction provided, to the proper Poor-law authorities for relief.—Sir WILLIAM ANSON said: Such a circular as is proposed could not properly be issued by the Board of Education without the concurrence of the Local Government Board. I will consider the matter.

Sir JOHN GORST asked the President of the Local Government Board whether he would address a circular to the local Poor law authorities pointing out the duties of relieving officers in reference to giving medical and other relief to destitute children irrespective of the conduct and character of their parents, and whether the Local Government Board would suggest that in case of relief in kind given to destitute children part of such relief should be in the form of milk.—Mr. GERALD BALFOUR said: My reply to the question of my right honourable friend must be to the same effect as that which I gave on the 17th inst. to a somewhat similar question put to me by the honourable Member for the Ilkeston Division. I am not aware of any reason for supposing that boards of guardians and their officers are not alive to the powers and duties which attach to them in relation to destitute children, where application is made to them for relief. With regard to the latter part of the question I think that boards of guardians may be trusted to use their discretion as to the giving of milk as outdoor relief to destitute children. The Local Government Board called the attention of its inspectors to the subject last year. It does not appear to me to be necessary to issue a circular as suggested.

Later in the day a discussion arose on the same subject, an opportunity being afforded on the second reading of the Consolidated Fund Bill.

Dr. MACNAMARA said that the real practical education difficulty was not the religious question but how they were to deal adequately with the needs of the physically unfit.
ther have a
well set-up, well clothed, well-fe
nan than a
rickety, weak-kneed, weak-chested
vice versâ.
Two things must be done. First in the very poor slum schools the children must be kept under permanent medical supervision. There were at present in London three or four medical officers whose services were utilised, but if the needs of London were looked after like those of Brussels there would be about 100 medical officers so employed. Secondly, the canteen scholar system of Paris must be adopted. It was a perfectly simple system partly maintained by voluntary subscriptions, partly by payments made by the parents, and partly by a grant made by the State. Under such a system in slum areas schools would be linked together, four or five in each group, and for each group there would be a central dining hall. The parents would obtain dinner coupons; if they could pay they would do so; if not they would get them gratuitously.

Sir JOHN GORST said that the number of children sacrificed to the Moloch of industry owing to the unfavourable conditions before and after birth induced by the mothers working in factories was enormous. In Lambeth the other day about two dozen cases of starving children whose condition was vouched for by a medical officer were reported to the Board of Education. The board of guardians when asked to relieve the children passed a resolution wh
desired but it had been reported t
been relieved. There would be no
bringing about medical examinatio
necessary was to put a clause in the Code to the effect that after a certain date no grant would be paid to any public elementary school unless there was a satisfactory system of medical inspection approved by the Boar

Dr. C. T.
without foo

impossible f
work. He admitted the necessity for inquiries but they should do something in the meantime to prevent the physical deterioration arising from that early malnutrition which engendered a desire for stimulants and increased the number of unemployed and unemployable.

Sir WALTER FOSTER said he the
the
Board of Education to encourage
the
schools. Medical relief was not
why
should the feeding of children at school? On the recommendation of the teacher the children of destitute parents might be fed, the relief being given as medical relief was now given, on loan. The cost could be recovered from the parents where they were capable of paying.

Sir WILLIAM ANSON, in the course of his reply, said that the suggestion that the Poor-law authority in areas where distress was known to prevail should provide the meals on proper evidence and that the
parei
orthy to be taken
into
with the President
of th
t was possible to
orgai
ren were not left
desti
er districts of the
large
It with neglected
child
underfeeding? It
coul
by raising money
from the rates or by voluntary effort.

Dr. HUTCHINSON: Or by all three.

Sir WILLIAM ANSON said he would not be prepared to make any suggestion as to grants from the Exchequer; and as to the rates he thought there was great force in the observation that it would be a hardship on the poor ratepayer to provide meals for a fellow citizen one degree poorer than himself. All he could do was to undertake that as far as administration went he would see what could be done to instruct local authorities to organise voluntary efforts.

Plague in India.

Mr. HERBERT ROBERTS asked the Secretary of State for India whether he would give the latest figures as to the number of deaths from plague and small-pox in India; whether he would state the number of deaths from plague since Jan. 1st, 1905; and whether he was in a position to make a statement as to what special steps the Government of India was taking to reduce the rate of mortality and to prevent the spread of the disease.—Mr. BRODRICK said: I am unable to give figures regarding deaths from small-pox as they are not specially returned to me. For plague the latest received figures are for the month of February—namely, 126,041 deaths. The total number of deaths from plague since Jan. 1st up to the end of February is 252,567. I have been in communication with the Viceroy as to whether more can be done to remedy the present deplorable loss of life. It has been decided to s
ition to make a thorough investi-
gation into
plague. The Royal Society and
the Lister
the direction of the inquiry and
arrangements for starting it at once have been made.

Mr. SCHWANN asked whether plague had not something to do with want of food owing to the enormous burdens placed upon the Indian people.—Mr. BRODRICK said: We have no evidence to that effect. It is almost impossible to trace any special cause for the increase in the number of deaths but there is one satisfactory feature which is that the number of infected areas has not increased.

Irish Guardians and Medical Appliances.

Mr. O'SHEE asked the Chief Secretary to the Lord Lieutenant of Ireland whether the Lismore board of guardians had by resolution requested the Local Government Board for Ireland, in view of the efforts now being made for the promotion of Irish industries and manufactures, to authorise them to entertain only tenders received from bonâ-fide Irish manufacturing firms for medicines and medical and surgical appliances; and, if so, whether the Local Government Board would give the Lism
ther public bodies
desiring to follow the sam
in the case of all
articles manufactured in
firms sufficient to
insure adequate competiti
ld make inquiries
of the President of the
d for England to
ascertain whether this principle was adopted by a considerable number of boards of guardians in England.—Mr. LONG replied: The duty of the board of guardians in the exercise of their public trust is to have due regard to economy and to obtain the best return possible for the money of the ratepayers whom they represent. The Local Government Board has no power to enlarge or to curtail the responsibility of the guardians in this respect. The English Local Government Board has no knowledge that the method suggested is adopted in this country.

Laboratory Work at Birmingham.

Mr. LEIF JONES asked the Chancellor of the Exchequer whether he was aware that the School of Brewing in connexion with the University of Birmingham had not fulfilled the expectations of its founders; that to provide against the closing of the school a professional laboratory, in competition with private analysts, was to be established for the purpose of analysing brewers' samples; that it was proposed to advertise the existence of the laboratory to the brewing trade generally; and that the local brewers, in consideration of having guaranteed a sum toward the maintenance of the school, were to have their analytical work done at the school laboratory free of cost to the extent of their respective guarantees; and whether he would take steps to prevent an institution supported partly out of public funds being th
with private professional analysts.—Mr. A
I am informed that the School of Brewing
expectations of its founders and is now in a
w
C
ds
Government grant has been used in founding or carrying on the

school. The scientific work done in the school is the subject of a complimentary reference from the gentleman who carried out the last

for any Treasury interference.

TUESDAY, MARCH 28TH.

Typhoid Fever at Malta.

Sir JOHN COLOMB asked the Secretary to the Admiralty whether during the year 1904 there were many cases of typhoid fever in His Majesty's ships resorting to Malta Harbour.—Mr PRETYMAN replied: In H.M.S *Venerable* there were 17 cases of typhoid fever, four ending fatally, in H.M.S *Montagu* six cases and one death, and in H.M.S. *Arrogant* four cases and one death As such questions and answers give rise to misapprehension I think it desirable to add that the outbreaks of typhoid fever in these ships were not due to the Malta water supply. The disease was contracted during the visits of these ships to other Mediterranean ports

Medical Officers of Health and Private Practice

Mr. WEIR asked the Lord Advocate whether he would state the names of the six counties in Scotland where the medical officers of health engaged in general or consultative practice; and whether

ficers to give their whole time

appointments were made.—The

the counties are Bute, Forfar,

ss and Cromarty. Since 1901 it

Notes, Short Comments, and Answers to Correspondents.

THE OPHTHALMIC OPTICIAN.

A correspondent has forwarded to us a card which was dropped into his letter box. The card emanates from a firm of opticians named Robinson and Co. who live in Bishopsgate and Messrs. Robinson keep an "optologist" who bears the singularly inappropriate name, for one who deals with the sight, of Moles. Mr. Moles states that he holds diplomas by examination from the British Optical Association and from the Worshipful Company of Spectacle Makers. Messrs. Robinson profess, we presume through Mr. Moles, to relieve various errors of refraction and also sore eyes or watery eyes. They say: "Our system of sight testing is thorough and we can detect the cause of the eye trouble or the slightest defect of vision." Though it may be that an "optologist" can detect and even relieve simple cases of errors of refraction, there are many cases of eye trouble which are dependent upon other causes, and Messrs. Robinson and Moles are quite capable of doing irreparable damage by preventing persons affected by, say, glaucoma in an early stage, from seeking proper medical advice. They would be well advised to stick to their proper occupation of making optical instruments.

THE LORD OF THE MANOR'S HERIOT AT AN INQUEST.

To the Editors of The Lancet.

Sirs,—On reading some old letters from an ancestor of mine I came across a curious circumstance in connexion with an inquest which is interesting, although no doubt familiar to those acquainted with the history of legal matters. One dated April 20th, 1794, from a father in Westmorland to a son in London, relates how "Your brother Joseph rec'd a blow last Tuesday over his bowels by one of his own Horses, and being in excrutiating pain till Sunday morning, at Eight o'clock, he then expired. We had two doctors to attend him but all in vain. ......" The next, dated May 4th, 1794, relates "In my last I gave an account of your Bro' death; which was the same day I wrote unto you. It was attended with very unpleasing circumstances which I shall relate as follows. Sunday morning near Eight o'clock he Died, on Monday we had a report that the Coroner would take an Inquest on the Body, which accordingly on Tuesday (that being the day of his Burial) he, together with the Jury, did the same. They then brought in the Stagg to be a forfiture due to Lord Lonsdale, but the Jury brought in the unlucky Beast in Value as low as Three pounds, thinking that sum would be a compencation to his Lordship: but, alas! it proved altogether abortive, for the next day, being Wednesday, early in the morning, A. Medcalf, being his Baylif, came and made a demand of the stagg which we imediately deliver'd up. I then was resolved to write a letter to his Lordship Last Monday Morning. I sent the letter with your Bro. John and Cousin Thos Scarborough; they waited for an Answer from his Lordship till Wednesday at Twelve o'clock at night: when to their great surprise his Answer was that If they pleas'd they might take the stagg again by giving him the small trifle of Two guineas, and seemed quite happy if he could please his friends with such a small favour, as he called it ......" Apparently it was the custom in those times in cases of inquests for the relatives to pay a forfeit to the lord of the manor. *The* stag is written as if that were the special penalty where such was available.

I am, Sirs, yours faithfully,

City-road, E.C., March 20th, 1905. J. J. Udale.

⁂ "The stag" was chosen as a heriot in this case probably because no more valuable animal was available, unless the whole proceeding depended on some local legal formality of which we have no record.—Ed. L.

DOVER AS A HEALTH RESORT.

To the Editors of The Lancet.

Sirs,—Could any of your readers give me any information about Dover as a health resort? Could they also inform me whether the medical officer of health issues a yearly statement of the health and statistics of the borough of Dover; if so, where it is to be had; the source of the water-supply and the rainfall, and whether it is a desirable place residentially. I have endeavoured to get the medical officer of health's report but have failed so far.

I am, Sirs, yours faithfully,

March 26th, 1905. Paddington.

FIREMEN'S SMOKE HELMETS.

In its engineering supplement the *Times* of March 29th mentions that the Manchester Fire Brigade is now in possession of a few specimens of a new "smoke outfit," which it is expected will be very useful to the firemen when working in presence of dense smoke or noxious fumes. A helmet having a glass door in front is fastened round the neck by means of a cloth attachment and when the door is closed the dangerous atmosphere is effectually excluded from the fireman's head and face. A flexible metal tube supplies him with air which is pumped from a special steam engine. Electricity is als supplied for a telephone fixed in the helmet to enable its wearer t communicate with the outside and for the electric lights which th fireman equipped with the outfit will carry.

FLANNELETTE.

To the Editors of The Lancet.

Sirs,—I must apologise to "A Surgeon" for not having immediatel replied to his letter of Feb. 25th but the fact is I managed somehow t overlook it and only to-day, in turning over the back numbers, have I come upon his short but very interesting note. If he (or anyone els interested in the matter) will send his address to the patentees o "Non-Flam" (Aytoun-street, Manchester) they will be happy to giv him information as to where he can obtain the cheaper makes of thei non-inflammable flannelette and also to answer any other inquirie which he may make about it.—I am, Sirs, yours faithfully,

Castleton, Lancs., March 27th, 1905. S. Bradbury.

SANATORIUMS.

To the Editors of The Lancet.

Sirs,—I should be glad if any of your readers would be good enough to inform me if it be possible to obtain a complete list of sanatoriums in this country for the treatment of phthisis.

I am, Sirs, yours faithfully,

March 27th, 1905. D.P.H.

L.R.C.P.—We think from what our correspondent tells us that the General Medical Council might well have taken notice of the unprofessional procedure. There is, we fear, no other tribunal before which the offender can be brought.

H. H. Toronto.—The condition is a common one. Our correspondent should consult a medical man.

Communications not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SATURDAY (8th).—ROYAL [illegible] street, Bristol).—11 A.M. [illegible] on Isolation Hospitals ([illegible] Yabbicom). Dr. C. Wint[illegible] H. Jones, Dr. J. Howar[illegible] Mr. J. T. Thomas, Dr. [illegible] part in the discussion. General discussion is invited.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing [illegible] *should be marked and addresse*[illegible]

Letters relating to the [illegible] *rtising departments of* THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. II. of 1904, which was completed with the issue of Dec. 31st, and the Title-page to the Volume, were given in THE LANCET of Jan. 7th.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1904 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.	
One Year	£1 12 6
Six Months	0 16 3
Three Months	0 8 2

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTICE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

During the week marked copies of the following newspapers have been received:—*Westminster Gazette, Express and Echo (Exeter), Surrey Advertiser, Reading Mercury, Mining Journal,* [illegible] *Chronicle, Standard,* [illegible] *y, Halifax Courier,* [illegible] *Windsor and Eton Express, Guernsey Star, Belfast Whig, Northern Mail, Pall Mal Gazette, &c.*

Communications, Letters, &c., have been received from—

A.—Mr. J. Astier, Asnières; Aerators, Ltd., Lond.; *Archives of Physiological Therapy*, New Haven, U.S.A.; A. G. G.; Messrs. Adlard and Son, Lond.; A. J. L; Admiralty, Medical Department, Director General of; Madame Alexandrescu, Bucharest.

B.—Dr. A. Balfour, Khartoum; Mr. T. H. Body, Leigh; Mr. C. Birchall, Liverpool; Messrs. Burroughs Wellcome and Co., Lond.; Messrs. Barnett and Shirer, Lond.; Dr. H. Charlton Bastian, Lond.; British Medical Association, General Secretary of; Mr. S. Bradbury, Castleton; British Medical Association, North of England Branch, Newcastle-on-Tyne, Secretary of; Messrs. Bedford and Co., Lond.; Mr. S. C Bloxham, Ebbw Vale; Dr. J. Bell, Hong-Kong.

C.—Dr. J. Campbell, Lond.; Mr. William Carter, Liverpool; Mr. Phillip Carr, Lond.; Chester County Asylum, Secretary of; Messrs. Cock, Russell and Co., Lond.; Dr. F. Carron, Chable; Cosmo Chemical Co., Lond.; Mr. A. E. Charlesworth, Elstree; Chesterfield and North Derbyshire Hospital, Secretary of; Messrs. Cornelius and Boulter, Cheltenham; Cheltenham General Hospital, Secretary of.

D.—Dr. A. Duncan, Lond.; Messrs. Duncan, Flockhart and Co., Lond.; Dr. Daniel, Epsom; Denver Chemical Manufacturing Co., Lond.; Derbyshire Royal Infirmary, Secretary of; Dr. Edward H. Douty, Cannes.

E.—Messrs. Evans, Gadd, and Co., Exeter; East Suffolk and Ipswich Hospital, Secretary of; Ebbw Vale Workmen's Doctors' Fund, Victoria.

F.—Mr. Robert Fenner, Lond.; "Fresh Air"; Dr. and Mrs. C. Owen Fowler, Lond.

G.—Miss P. Graham, Ecclefechan; Mr. Walter Gregory, Lond.; Mr. Walter P. Greenfield, Lond; Guy's Hospital, Lond., Treasurer of; German Hospital, Lond., Secretary of; Messrs. Gordon and Gotch, Lond.; Mrs. Green, Gainsborough.

H.—Miss F. Haas, Bad Kissingen; Mr. C. Harris, Bournemouth; Hotel Tariff Bureau, Lond.; Miss Hopkinson, Taunton; Captain L. W. Harrison, R.N., Lond.; Mr. T. Hart, Scarborough; Messrs. Haasenstein and Vogler, Frankfurt; Messrs. J. Haddon and Co., Lond.; Hill End Asylum, St Albans, Clerk of; Dr. W. S Handley, Lond.; Dr. S. H. Habershon, Lond.; Sir Victor Horsley, Lond.; Dr. William Hunter, Hong Kong; Mr. W. H. Haw, Knynsa; Dr. Francis H. Hawkins, Reading; Hull Royal Infirmary, Secretary of.

I.—Ingham Infirmary, South Shields, Secretary of.

J.—Dr. W. Black Jones, Llangammarch Wells; Messrs. Jacob and Johnson, Winchester.

K.—Dr. George Keith, Currie, N.B.; Messrs. Knoll and Co., Lond.; Messrs. P. S. King and Son, Lond.; Messrs. R. A. Knight and Co., Lond.

L.—Dr. Arthur Latham, Lond.; London County Council, Clerk of; Dr. Ferguson Lemon, Hawthorn, Victoria; Dr. Alfred [illegible] Messrs. Lalonde Bros. and Pasham, Weston-super-Mare; Messrs. Lee and Nightingale, *Liverpool; The Baroness K. Leonhardy*, Villars sous-Mont; Mr. F. F. Leighton, Bristol.

M.—Mr. J. W. Midgley, Keighley; Maltine Manufacturing Co., Lond.; Mr. R. Mosse, Berlin; Dr. G. N. Meachen, Lond.; Professor B. Moore, Liverpool; Manchester Hospital for Con- [illegible] Biggleswade; Mr. J. McLaren, Lond.

N.—Messrs. Novello and Co., Lond.; Dr. J. O'Neil, Oxford; National Dental Hospital, Lond., Dean of; National Health Society, Lond., Secretary of; Mr. J. C. Needes, Lond.; Mr. H. Needes, Lond.

O.—Mr. T. H. Openshaw, Lond.; Dr. Henry O'Neill, Belfast.

P.—Dr. Peter Paterson, Glasgow; Pioneer Milk Sugar Co., Lond.; Dr. A. C. Profeit, Ballater; Mr. F. G. Parsons, Lond.; Messrs. Parke, Davis, and Co., Lond.; Dr. F. Craddock Palmer, Alverstoke; Mr W. H. Payne, Lond.; Paddington, Medical Officer of Health of; Pearson's Antiseptic Co., Lond.; Messrs. Peacock and Hadley, Lond.

Q.—Queensland, Department of Public Health, Brisbane, Secretary of.

R.—Mr. J. Robinson, Lond.; Mr. T. E. Rickerby, Cheltenham; Messrs. Roberts and Evans, Aberystwyth

S.—Dr. F. M. Sandwith, Cairo; Mr. K. S. Sodhi, Bhatinda, India; Messrs. Spiers and Pond, Lond.; Messrs. W. B. Saunders and Co., Lond.; Dr. F. W. Saunders, Luxor; St. Mungo's College, Glasgow, Secretary of; Society for the Study of Disease in Children, Lond., Hon. Secretary of; Mr. Robert Smith, Glasgow; Mr. E. W. H. Shenton, Lond.; Society of Apothecaries of London, Clerk of; Dr. K. Scott, Cairo; Stirling District Asylum, Larbert, House Secretary of; Scholastic, Clerical, &c., Association, Lond.

T.—Mr. A. Turton, Reading.

V.—Dr. H. Vincent, Paris.

W.—Dr. Forbes Winslow, Lond.; Mr. C. Williams, Rock Ferry; Mr. D. Welsh, Egham; Mr. C. [illegible] J. Wright and Co., Bristol; [illegible]

Letters, each with enclosure, are also acknowledged from—

A.—Mr. E. Arnold, Lond.; Dr. L. Anderson, Bishop's Waltham; Messrs. Armour and Co., Lond.; A. L.; A. V. W.; *American Medicine*, Philadelphia, Manager of; A. C. S.; Anglo-American Pharmaceutical Co., Croydon; A. V. C.; A. C. L.; A. J. A.; Ashton-under-Lyne District Infirmary, Secretary of.

B.—Mr. A. D. Brookes, Lond.; Dr. W. Blair Bell, Aigburth; Mr. J. A. Bickle, Clifton; Mr. R. A. Bickersteth, Liverpool; Mr. R. S. Betts, Bournemouth; Mr. H. Bourne, Halling; Mr. A. E. Barker, Lond.; Mr. J. P. Barry, Cork; Birkenhead Union, Clerk of; Mr. W. A. Berridge, Redhill; Mr. A. H. Buck, Hove.

C.—Miss Clarke, Newport, Mon.; Condensed Egg Syndicate, Lond.; Miss N. Court, Duffield; Messrs. T. Christy and Co., Lond.; Miss E. Cobb, Foots Cray; Dr. J. T. Callcott, Gosforth; Messrs. Clarke, Son, and Platt, Lond.; C. J. N.; Mr. F. W. Clarke, Chorlton-cum-Hardy; Mr. J. J. Crowley, Cork; Cameron Hospital, West Hartlepool, Secretary of; Mrs. Cufaude, Lond.; Messrs. Crossley and Co., Lond.; Mr. J. W. Culmer, Epsom; Carmarthen Infirmary, Secretary of.

D.—Mr. H. Work Dodd, Lond.; Messrs. W. Duff and Co., Lond.; Mr. N. R. Dharmavir, Edinburgh; D. G. B.; Mr. J. Diggens, Lancaster; Mr. R. Daniel, Lochgilphead; Dowsing Radiant Heat Co., Lond., Secretary of.

E.—E. R. B.

F.—Dr. C. Fraser, Menston; F. D.; Miss Fraser, Ringwood; Messrs. Folkard and Hayward, Lond.; Franklin Co., Toledo, U.S.A.; F. C. W.; F. W. B.; Messrs. Fletcher, Fletcher, and Co., Lond.

G.—Mr. I. Gundelfinger, Lond.; Messrs. F. Gould and Co., Lond.; Messrs. Grimwade, Ridley, and Co., Lond.; G. T. H.; Miss J. Gauld, Lond.

H.—Mr. J. H. Heaton, Cambridge; Mr. J. T. Hyatt, Shepton Mallet; High Shot House, Twickenham, Medical Superintendent of; Dr. F. W. Hewitt, Lond.; H. S.; Herdmans, Ltd., Sion Mills; Mr. M. M. Hutchinson, Polperro; Mr. J. Howard-Jones, Worthen; Holloway, &c., Dispensary, Lond., Secretary of; Mr. T. Harling, Muker; Dr. E. C. Hulme, Rotherham.

J.—Dr. W. Jamison, Aber Bargoed; Dr. W. W. Jones, Ledbury; J. H. L. T.; J. H. M.; J. P. S.; Dr. L. C. Joel, Bunbury.

K.—Kny Surgical Co., Lond.; Dr. H. Cameron Kidd, Bromsgrove; Messrs. Knight, Frank, and Rutley, Lond.

L.—Dr. J. S. Low, Dewsbury; Miss F. Leech, Lond.; Lancashire County Asylum, Rainhill, Clerk of; Mr. R. R. W. Logan, Ashby-de-la-Zouch; Dr. F. J. Lidderdale, Lond.; Miss Leycester, Lond.; Mr. J. Levin, Lond.; Dr. A. H. N. Lewers, Lond.

M.—Mr. W. Martindale, Lond.; Mr. C. Mansell Moullin, Lond.; Dr. W. Mackie, Elgin; Messrs. May, Roberts, and Co., Lond.; M. D., Kettering; M. S. M. D.; Dr. W. R. Mander, Stockport; Dr. C. R. Martin, Annfield.

The Goulstonian Lectures

ON

SOME CONSIDERATIONS ON THE NATURE OF DIABETES MELLITUS.

Delivered before the Royal College of Physicians of London on March 16th, 21st, and 23rd, 1905,

By W. CECIL BOSANQUET, M.A, M.D Oxon, F R C P Lond,

ASSISTANT PHYSICIAN TO CHARING CROSS HOSPITAL AND TO THE BROMPTON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST FORMERLY FELLOW OF NEW COLLEGE, OXFORD

LECTURE I

Delivered on March 16th

Mr President and Gentlemen,—I must first thank you for the honour which you have conferred upon me by inviting me to deliver these lectures—an honour which I very highly appreciate but which has nevertheless proved to me a source of considerable embarrassment Indeed, the hesitation which I at first felt about undertaking the duties of the post has since been strengthened into an assured conviction that it was only too fully justified It must always, I think, be a task of great difficulty for one of the junior Fellows of this College to deliver a lecture before his seniors who must needs be better acquainted with all the facts of medicine than he, and the difficulty is specially great in the case of one who, like myself, is attached only to a comparatively small hospital where material for study is much less than that available at our larger institutions Fortunately, it has been wisely arranged that the Goulstonian lecturer should deal mainly with pathology—the theoretical side of disease—rather than with clinical phenomena or treatment And as pathology is a constantly advancing science it may be profitable at times to review some of the facts recently ascertained and the hypotheses put forward to explain them, if only to elicit the truth that there are still very lamentable gaps in our knowledge upon all medical subjects and that the continual stream of medical writings rather conceals than fills in these deficiencies

In choosing for my subject the nature of diabetes I am conscious that I may appear guilty of more than ordinary presumption, inasmuch as it is one which has been most exhaustively investigated by one of the senior Fellows of this College who has made the subject his own and attained therein a position of authority which is recognised throughout the civilised world Dr F W Pavy, by his careful and illuminating researches into the physiology of the assimilation of carbohydrate food has thrown light into some of the dark corners which abound in the field of diabetes Yet he himself would readily, I think, admit that the nature of the disease is still far from being finally determined, that there are many problems awaiting solution and scope for much further research and speculation

As it was the original intention of the founder of these lectures that they should be devoted to demonstration of morbid anatomy, so I hope to deal mainly with the relation of the disease to structural alterations in the organs recognisable after death, and to discuss the reasons which exist for associating any one of them causally with the existence of diabetes But in recent days all the great advances in pathology have been made by means of experiments on living animals and I would refer also to the results of some such researches which have appeared to give rise to conditions resembling the human malady Lastly, there have in the last few years been promulgated theories connected with the resistance of the body to parasitic invasion which have involved conjectures as to some of the processes by which food is assimilated by the tissues It may be not wholly uninteresting though unfortunately premature so far as certainty is concerned, to speculate as to the bearing of these theories on the pathology of diabetes

Definition of Diabetes

In the discussion of any matter it is advisable to make some attempt to define the terms which we are using and it may be useful at the outset to consider for a moment what it is that we mean when we speak of diabetes mellitus It is true that definition is impossible in science before we know all about the phenomenon which we wish to define, and for this reason final definitions are practically unattainable, except in abstract reasoning such as mathematics, since knowledge of natural phenomena and their causes is constantly growing In the field of medicine we can see the process of modification of our ideas in accordance with the advance of knowledge constantly at work Thus originally, as Allbutt has pointed out, diseases were groups of symptoms which recurred in association sufficiently frequently to constitute a definite idea No doubt scientifically minded persons early realised that these groups were the outward and visible signs of altered conditions of the body, but of the nature of the condition present in each case they had no knowledge Later it was found that certain structural alterations were invariably associated with the symptoms of many diseases and these underlying physical conditions assumed more and more importance in the connotation of the name of the disease In these instances the stage of morbid anatomy had been reached Later still we have acquired a knowledge of the causes of certain diseases and of some at least of the means by which they produce their characteristic symptoms This knowledge is only definite in the case of some of the infective diseases, such as tetanus or tuberculosis, in which we can isolate the pathogenic bacteria investigate the poisons which they generate, and unravel to some extent their modes of action and the defensive reactions of the infected organism

In the case of many diseases we are still in the stage of morbid anatomy, examples are seen in the various anæmias, of which nothing more is known than the alterations in the constitution of the blood In diabetes we have hardly as yet attained to even this stage of knowledge Attempts have, indeed been made to show that changes are invariably to be found after death in the pancreas, of which I hope to say more in my next lecture, but at present there is no consensus of opinion as to the constancy of these changes—or rather, it has been pointed out there are many cases of the disease in which no alterations in this organ can be demonstrated so that there seems a danger of even this association—the most hopeful prospect of establishing the disorder on an anatomical basis—proving elusive Yet we know that it is impossible for perversions of function to occur in normal circumstances without coexistent alteration of structure, since function is merely structure undergoing change, as was pointed out by G H Lewes many years ago, so that if the conditions of the cell remain the same and its structure the same the function must continue the same likewise In other words all functional defects must arise from structural lesions, whether these are gross, or microscopical, or ultra microscopical

In the case of diabetes the gradual alteration in the connotation of the name can be easily recognised In the earliest times, when the name was first invented, there can be no doubt that all conditions accompanied by polyuria were classed together, to all the comparison of the patient to a syphon transmitting a continual stream of water was [illegible] The discovery of the existence of sugar [illegible] was made late in the history of [illegible] was unknown till some hundreds of years after the commencement of the present era and in the West it remained undiscovered till the time of our countryman, Willis, towards the end of the seventeenth century who noted the sweet taste of the urine The actual proof of the presence of sugar was afforded a little later by Dobson The spirit of Western inquiry, as contrasted with Eastern apathy, is well exemplified by the rapid growth of information on the subject which followed Willis's discovery The writer of an anonymous medical treatise on diabetes, published at Oxford in 1745, notes that the disease was then attracting much attention and discussion, and up to the present time an ever increasing volume of writings has centred round its pathology

Since the discovery of sugar in the urine and the resulting separation of saccharine from insipid diabetes and from other causes of polyuria further steps in the subdivision of the subject have been made In the first place, it is recognised that all cases in which there is sugar in the urine are not diabetes mellitus. Glycosuria is now known to be a possible accompaniment of many diseases having no apparent connexion with the malady with which the condition was first associated. Cerebral injuries, many nervous conditions, Graves's disease, and other maladies may be accompanied by glycosuria, yet we do not call them diabetes. We have then to inquire what criterion exists for the identification of true diabetes as apart from such conditions of symptomatic glycosuria and the question is not easily answered. It would seem that our only grounds in most cases for asserting that a patient is suffering from diabetes are the amount and the persistence of the glycosuria. It is manifest that such criteria are unsatisfactory. Taken separately each would be fallacious. A considerable quantity of sugar may exist at any one time in the urine apart from diabetes. I well remember a patient having been brought into Charing Cross Hospital one night comatose, with a fairly large amount of sugar in the urine. He was supposed to be suffering from diabetic coma and was treated somewhat energetically by bleeding and infusion of saline solution. At the necropsy the case was found to be one of cerebral hæmorrhage, yet the quantity of sugar in the urine had been considerable. On the other hand, if permanency of the glycosuria is to be the necessary condition for distinguishing diabetes we should be unable to admit that a case could ever be cured, nor could the condition be satisfactorily diagnosed until the patient was dead. The old Greek proverb that we should call no one fortunate till he was dead, because a reverse of luck might at any time occur, was perhaps a wise piece of advice, but it would be unsatisfactory in medical practice, where it would sometimes seem that the assignment of a name to a disease is only less gratifying to the patient than its cure or alleviation. We cannot base the definition of a disease upon its insusceptibility of cure. And if we ask how long the glycosuria must last before we can call a case diabetes it is not easy to give an answer. Yet in diabetes, in the absence of any ascertained morbid anatomical changes invariably associated with the disease, we seem compelled to rely for grounds of diagnosis and even of definition upon the amount and persistence of the glycosuria. How unsatisfactory this is will be readily apparent when we consider what our position would be if we knew only the fact of the existence of albumin in the urine in certain conditions, without possessing any knowledge of structural changes in the kidneys, or if we were similarly limited in our knowledge in the presence of hæmaturia. We might perhaps get as far as recognising the existence of mild "functional" conditions in which the disorder cleared up without difficulty and grave cases of organic disease which rapidly went downhill—and that is about as far as we have got in the study of diabetes—but exact knowledge would be quite impossible.

As a sign of the present unsatisfactory results of attempts to define diabetes it is sufficient to indicate the conditions at present grouped under the term. Tyson gives the following varieties of glycosuria, to all of which the name diabetes is sometimes applied, arranged according to their causes: (1) alimentary glycosuria due to imperfect assimilation of carbohydrates; (2) glycosuria due to over-production of glucose from the hepatic glycogen; (3) vaso-motor glycosuria, owing to too rapid passage of glucose through the liver, without being converted into glycogen; (4) defective oxidation of glucose in the system (this form he associates with pancreatic and suprarenal disease); and (5) incurable diabetes, in which proteid is converted into sugar, including the fixed proteid of the tissues (this is accompanied by acid intoxication.) The group of disorders included in this list is manifestly made up of a heterogeneous collection of but slightly connected conditions which only our ignorance of the nature of the phenomena leads us to classify under the same term. It seems possible that some at least of the obscurity in which the subject of diabetes is wrapped arises from a failure to distinguish the disease from conditions which simulate it and that we must here apply the old maxim *divide et impera* and subdivide the group before we can extend the realm of knowledge.

Alimentary and composite diabetes.—In this direction an important division has been made in the subject by the distinction drawn between two forms or stages of diabetes mellitus—between cases on the one hand in which apparently the sugar which emerges in the urine is derived entirely from the carbohydrate materials contained in the food and cases in which, on the other hand, some of it, at all events, is formed by breaking down of the tissues of the patient. To these the names of "alimentary" and "composite" diabetes have been assigned by Pavy. This brings us to one of the remarkable points about the disease to which it is, perhaps, curious that more attention has not been paid. In many instances the first stage of the malady is signalised only by an alimentary glycosuria—that is, by an apparent inability to assimilate any considerable quantity of carbohydrate food. In the later stages the same patient not only cannot assimilate this kind of food but he also suffers from an actual breaking down of his own tissues into sugar. It is difficult to believe that the two conditions are the same in any way or that one can really pass into the other. To suppose that the presence of excess of sugar in the system acts poisonously and leads in time to a destruction of the body cells, of such a nature that the very poison at work is one of the products of the disintegration, is absolutely contrary to all analogy in vital chemistry. In cases in which special bodies are formed in the animal economy in response to the injection of toxic materials we find that the substance is of such a nature as to neutralise the effects of the poison, as in the process of immunising animals against certain vegetable poisons (abrin, ricin, &c.) or against the toxins of bacteria. In the case of the commoner poisons, mineral and organic, no such antitoxic power is, indeed, exhibited; but no instance of the actual poison itself being formed by the cells as a result of its own action is known. It is unlikely, then, on general grounds that sugar should form a special exception and cause breaking down of the cell protoplasm into sugar. There is indeed, no proof, so far as I am aware, that it is actually a poisonous substance. It appears to be a normal constituent of the blood, though existing there in very small quantities; and in default of direct evidence we should suppose that the only evil effects which it would be likely to exert would be by increasing the density of the plasma and thereby altering the osmotic pressure relatively to the surrounding tissues and to the formed elements of the blood.

The facts just mentioned—namely, the existence of alimentary and composite forms of diabetes—appear to constitute the ground-work of our knowledge of the disease, in which everything else is largely a matter of speculation and conjecture. We know that in the early stages of many cases of diabetes it is possible entirely, or almost entirely, to prevent the appearance of sugar in the urine by diminishing the amount of carbohydrate material given in the food. The inference seems necessarily to be that the sugar in the urine is derived directly or indirectly from the matter ingested. On the other hand, we know that in severe cases and in the later stages of many cases which originally appeared to be instances of alimentary diabetes the sugar in the urine persists in the absence of all carbohydrate food—nay, more, in conditions of starvation, in the absence of all food of any kind whatever. Here it is equally necessary to believe that the sugar is derived from the breaking down of some substance forming part of the living body. These being the two most securely established facts with regard to diabetes it is, I venture to think, to the explanation of them and of their mutual relationship that it is most important to direct attention in any attempt to explain the nature of the disease. It is comparatively useless to explain one phenomenon without explaining the other simultaneously; any hypothesis which fails to embrace both together is defective *ab initio*.

It is necessary, then, to look about for some explanation of the phenomena of diabetes capable of embracing both alimentary and composite cases. Now we know that sugar may appear in the urine in many conditions which are not diabetes as a result of ingestion of saccharine food. On the other hand, we know of no other condition in which there is an internal formation of sugar by disintegration of materials existing in the body. Further, this latter feature is characteristic of the developed disease, when all the conditions are presumably best marked. It appears, then, reasonable to regard this internal formation of sugar as the essential characteristic of the disease and to turn our attention specially to this rather than to the alimentary factor. So far as I can judge the reverse procedure has generally been adopted in studying the disease and the result has been to leave what I believe to be the most striking feature of diabetes mellitus unexplained.

We have to ask, then, Is it possible to formulate any hypothesis, consistent with what we know of the phenomena of diabetes, which shall explain alimentary diabetes in terms, if I may so express it, of composite diabetes? Now it may

be taken as admitted that the sugar which appears in the urine is merely filtered off from the blood—in other words, that glycosuria presupposes glychæmia The sugar present in the blood may arise in any one of several ways—from increased ingestion of sugar in the food or from increased formation in the body, or from diminished elimination or assimilation of the amount normally present In alimentary glycosuria it would seem that the sugar reaches the blood by absorption from the intestine, in composite diabetes it seems that some of it comes from the breaking down of the tissues Have we any means of assuring ourselves that in either case only one process is at work? In the case of the latter condition it seems certain that there is no alimentary element coexisting, since in starvation no food is taken In the former case the same exclusion is not possible It is true that in alimentary
supply of carbohydrate food will
sugar in the urine, but this does
proof that such food is the sole
coexistence of an internal source
t be excluded Indeed, Seegen
instances may decrease the sugar
which appears in the urine but not that which exists in the blood Now the amount of sugar present in the blood is the resultant of the forces which respectively pour sugar into it and remove it, and sugar may be removed by assimilation as well as by excretion It is conceivable that the body may have the power of dealing with a certain quantity of this substance but not with more than a definite amount If the whole of this amount is formed within the body it is clear that any further quantity entering from the intestine will appear in the urine; while if a large proportion, but not the whole, of the amount is formed within the body then the quantity of sugar which can enter from the intestine without causing glycosuria will be so much less than in a normal person who either forms no internal sugar or only a comparatively small amount I venture to think that this possibility is at least worth considering as involving less difficulty in the explanation of the conversion of a case of alimentary glycosuria into one of composite diabetes than is involved in the supposition of the onset of a new pathological process In favour of an internal formation of sugar in diabetes may be quoted the observations of Kolisch that in bad cases a carbohydrate diet may cause no increase in the amount of sugar present in the urine, which may vary from day to day quite independently of the food taken If such a conception were admissible a certain amount of clearness would be gained for a definition of diabetes which would

ing in the urine, as the case grew graver and more internal secretion was formed, so the patient's tolerance for carbohydrate food would diminish, and finally, the amount of internal sugar would be so great as to appear in the urine even in the absence of any alimentary supply

It is not necessary to suppose that the amount of sugar which can be dealt with by the tissues without appearing in the urine is the same in all persons Thus von Noorden found that of two healthy men one was capable of assimilating 150 grammes of glucose administered to him, while the other exhibited slight glycosuria when thus treated Probably if enough sugar were given at once everyone would excrete some of it in the urine
so much as average persons are
but there is no reason why they
apart from an increased internal sugar formation, and as a fact they do not all so develop The power of assimilating sugar varies even in the same person in different circumstances, as a man who is working hard will eliminate less sugar in his urine, as the result of an overdose of this substance, than one who is at rest (Breul) Authors appear to differ as to whether carbohydrate food other than sugar itself, can produce alimentary glycosuria in healthy persons Theoretical considerations would appear to be on the side of Naunyn and others who affirm this possibility, since it is fairly established that a certain proportion of starchy food is converted into sugar in the alimentary canal (Ellenberger and Hoffmeister) In pathological conditions, such as fevers and alcoholism, it has been actually proved by Strauss that glycosuria may result from the ingestion of starchy food

CAUSATION

Leaving for the present the question of the essential nature of diabetes, we may turn our attention to the causation of the disease With regard to the causes which determine the onset of diabetes nothing new seems to have been revealed by recent research We may not now agree with Avicenna that the most important of these causes is the eating of quinces, or with Trnka de Krzowitz that "aquosi potus ac praeprimis tepidi abusus haud difficulter diabetem inducit,"[1] any more than with the supposition of the Rabbi Moyses that the drinking of Nile water was the most potent cause of the malady as he saw it in Egypt but our positive knowledge is not much greater than that of early writers The association of the disease with alcoholic habits was noticed by our forefathers in the medical profession Dolæus attributes the onset of diabetes to drinking cyder and Willis to indulging in Rhenish wine, and there seems to be no doubt that alcoholism may play a part in its causation

Another poison to which some importance has been attributed in the causation of diabetes is tobacco Stern states that not only does the excessive use of this narcotic protract the duration of an alimentary glycosuria and increase the quantity of glucose in the urine but that it seems to transform slight chronic glycosuria into severe diabetes He attributes the action of tobacco to the absorption of small doses of carbonic oxide in the process of smoking, sufficient to induce a chronic intoxication with this substance This theory seems scarcely probable, for, although it is known that poisoning with carbonic oxide may be accompanied by glycosuria, one would think that the amount of this gas absorbed by the mucous membrane of the mouth would be insignificent It is only in the case of those who inhale the smoke that such a cause would appear likely to be operative Perhaps some of the deleterious effects attributed to cigarette smoking may result in this way, but I do not know of any observations tending to connect diabetes with this form of indulgence in tobacco more than with any other Lorand notes that some of his diabetic patients confessed to being large smokers of cigars

The presence in the urine of glycuronic acid—a near ally of sugar—has been observed after intoxication with a large number of substances phosphoric acid, phosphorus, lactic acid, hydrochloric acid, strychnine, curare, arsenic, butyl chloral hydrate, morphine hydrocyanic acid, chloroform, and turpentine (Sydney Martin) To the form of diabetes which follows phloridzin poisoning and the injection of suprarenal extract I shall refer later

The influence of heredity is perhaps now more fully recognised than was formerly the case Thus, Tyson puts the hereditary cases down as one quarter of the whole number and other writers at an even higher figure, and with heredity we must class the racial incidence of diabetes which seems to affect a larger percentage of the population among the Jews and Oriental peoples than among Europeans The greater liability of Jews than of other races to suffer from diabetes has indeed been denied by Pollatschek, and statistics on the subject are liable to be fallacious, but on the whole the fact seems well established Thus Lorand has collected statistics from his own native town, in which there are 20 000 inhabitants, of these 3000 are Jews He finds that diabetes is rare among the Christian population but so common among the Jews that there is scarcely a family of any size which has not among its members some sufferer from this malady This same writer has investigated the question whether the children of diabetic parents are liable to suffer from alimentary glycosuria and thinks that the question can be answered in the affirmative—a consideration which may lend some further support to the belief in the hereditary character of the disease But the evidence adduced is not quite convincing as to the existence of this phase of heredity in any large number of instances

In spite of the well established fact of the appearance of diabetes as a sequel of an attack of some infectious disease, such as enteric fever, influenza, or diphtheria, little evidence exists which seems in any way to point to an infective cause of diabetes itself—that is to say, there is nothing to indicate that it is the direct effect of a toxin formed by a pathogenic bacterium The experiments of Charrin and Carnot, in which diabetes was produced by injection of cultures of micro organisms into the pancreatic duct, must be explained on the ground of the production of a pancreatitis rather than as proving the origin of diabetes from the direct effects of toxins The action of syphilis as a cause of diabetes is probably exerted in the same direction Schmitz examined the records of 4389 diabetic patients and among them he

---

[1] This appears to refer to polyuria a potu not to saccharine diabetes

diabetes mellitus. Glycosuria is now known to be a possible accompaniment of many diseases having no apparent connexion with the malady with which the condition was first associated. Cerebral injuries, many nervous conditions, Graves's disease, and other maladies may be accompanied by glycosuria, yet we do not call them diabetes. We have then to inquire what criterion exists for the identification of true diabetes as apart from such conditions of symptomatic glycosuria and the question is not easily answered. It would seem that our only grounds in most cases for asserting that a patient is suffering from diabetes are the amount and the persistence of the glycosuria. It is manifest that such criteria are unsatisfactory. Taken separately each would be fallacious. A considerable quantity of sugar may exist at any one time in the urine apart from diabetes. I well remember a patient having been brought into Charing Cross Hospital one night comatose, with a fairly large amount of sugar in the urine. He was supposed to be suffering from diabetic coma and was treated somewhat energetically by bleeding and infusion of saline solution. At the necropsy the case was found to be one of cerebral hæmorrhage, yet the quantity of sugar in the urine had been considerable. On the other hand, if permanency of the glycosuria is to be the necessary condition for distinguishing diabetes we should be unable to admit that a case could ever be cured, nor could the condition be satisfactorily diagnosed until the patient was dead. The old Greek proverb that we should call no one fortunate till he was dead, because a reverse of luck might at any time occur, was perhaps a wise piece of advice, but it would be unsatisfactory in medical practice, where it would sometimes seem that the assignment of a name to a disease is only less gratifying to the patient than its cure or alleviation. We cannot base the definition of a disease upon its insusceptibility of cure. And if we ask how long the glycosuria must last before we can call a case diabetes it is not easy to give an answer. Yet in diabetes, in the absence of any ascertained morbid anatomical changes invariably associated with the disease, we seem compelled to rely for grounds of diagnosis and even of definition upon the amount
and persistence of the glycosuria found that the is
will be readily apparent to the skull was only transient
would be if cases that in certain instances it may remain
albumi nent.
any k Experimentally many varieties of injury to the nervous
were system may produce glycosuria. Besides Bernard's "punc-
ha ture" and his operation of galvanising the central ends of
t' the cut vagi, destruction of the pons and of the posterior crura cerebri, section of the optic thalami, section of the medulla and of the cervical cord, extirpation of the cervical sympathetic, and other lesions have been followed by glycosuria. Stimulation of the depressor nerve has had the same effect and even section of the sciatic has done the same. Sciatica itself has been stated to cause diabetes but it is at least as probable that the nerve lesion was caused by the general disease as that the opposite sequence took place. An experiment illustrating the effect of nervous influence upon the excretion of sugar is seen in the expe-[illegible]nce that if a cat be merely fastened down upon the [illegible]ating table, without any further injury, sugar at once [illegible]ars in the urine, the so-called "*Fesselungsdiabetes*" of [illegible] Germans (Boehme and Hoffmann.)

Connected with the question of the nervous causation of diabetes is the discovery that glycosuria is common among the insane. It is said to occur more frequently in patients suffering from depressive forms of mental disease than among the more active varieties, which would suggest that in such cases there may be a failure either in the power of utilising sugar in the tissues or in the formation of some necessary secretion rather than an active production of sugar such as would seem to occur in the other nervous conditions which have just been mentioned. We must also bear in mind the hereditary nature of diabetes and its apparent tendency to appear in the offspring of neurotic stocks, other members of which have exhibited signs of more or less marked mental disease.

On the other hand, it is certain that only a small number of those persons who are exposed to the action of the causes just enumerated—continued hard work, shocks, and injuries —suffer from diabetes in consequence, and it is equally certain that the disease often occurs without the aid of any of these exciting causes. It is legitimate, I think, to question the reality of the causal nexus in some at least of the cases attributed to mental factors. It is difficult to be sure that we are not confusing *post hoc* with *propter hoc* in many such instances. Thus in the case of injuries and shocks it is to be borne in mind that these accidents cause patients, have been assigned by Pavy. This brings us to one of the remarkable points about the disease to which it is, perhaps, curious that more attention has not been paid. In many instances the first stage of the malady is signalised only by an alimentary glycosuria—that is, by an apparent inability to assimilate any considerable quantity of carbohydrate food. In the later stages the same patient not only cannot assimilate this kind of food but he also suffers from an actual breaking down of his own tissues into sugar. It is difficult to believe that the two conditions are the same in any way or that one can really pass into the other. To suppose that the presence of excess of sugar in the system acts poisonously and leads in time to a destruction of the body cells, of such a nature that the very poison at work is one of the products of the disintegration, is absolutely contrary to all analogy in vital chemistry. In cases in which special bodies are formed in the animal economy in response to the injection of toxic materials we find that the substance is of such a nature as to neutralise the effects of the poison, as in the process of immunising animals against certain vegetable poisons (abrin, ricin, &c.) or against the toxins of bacteria. In the case of the commoner poisons, mineral and organic, no such antitoxic power is, indeed, exhibited; but no instance of the actual poison itself being formed by the cells as a result of its own action is known. It is unlikely, then, on general grounds that sugar should form a special exception and cause breaking down of the cell protoplasm into sugar. There is indeed, no proof, so far as I am aware, that it is actually a poisonous substance. It appears to be a normal constituent of the blood, though existing there in very small quantities; and in default of direct evidence we should suppose that the only evil effects which it would be likely to exert would be by increasing the density of the plasma and thereby altering the osmotic pressure relatively to the surrounding tissues and to the formed elements of the blood.

The facts just mentioned—namely, the existence of alimentary and composite forms of diabetes—appear to constitute the ground-work of our knowledge of the disease,
accidentally associated. largely a matter of speculation
previously in six cases and pr early stages of many
12½ per cent. in which it might be most entirely, to
the malady. Gout was an association in diminishing
Toogood's observations as to the causation of g food.
poor are to be relied upon these cases also might With reg he
buted to the effects of indulgence in alcohol. heredity, there were six cases (two females and four males) in which other members of the patients' families had suffered from diabetes. The most striking instance was that of a man, aged 50 years, who had two brothers and one sister either suffering from or dead from diabetes. In each of the other instances only one other member of the family had been affected. In four cases (two males and two females) there was a family history of insanity or nervous disease. Taking them altogether, heredity was only discoverable as a possible causal factor in 12½ per cent. of the whole number, a much smaller proportion than is assigned to this cause by the writers whom I have previously mentioned. In the great majority of the cases no explanation of the onset of the disease was given by the sufferers. It had come on insidiously and as far as could be gathered spontaneously. Here, perhaps, I may remark upon the large number of instances among these cases in which complaint was made of abdominal pain—generally epigastric or hypochondriac. In one or two instances intestinal disturbances, such as diarrhœa and vomiting, had preceded the apparent onset of the diabetes sufficiently closely to attract the patient's notice and in three other cases jaundice had occurred at some previous period. These features may not be without interest in view of the possible connexion of diabetes with pancreatic disease.

MORBID ANATOMY.

I now turn to the morbid anatomy of the disease, the changes found in the different organs of the body in those who have died from diabetes. Ever since Claude Bernard's great discovery of the existence of glycogen in the liver and of the possibility of causing this substance to be discharged into the blood in the form of sugar by nervous action, the liver has received the greatest amount of attention in relation to the pathology of diabetes mellitus. Yet it can hardly be denied that the result has been on the whole disappointing. It must have seemed at first that there was at length a prospect of solving the mystery of this diseas which had remained "a marvel" since the time of Aretæus (θωῦμα τὸ διαβήτεω πάθος). But although it seems certain

the phenomena of glycogenesis and led to concentrate our attention upon a side issue.

The facts ascertained with regard to the presence of glycogen in various tissues s
a reserve of nutriment for
is found in the cells of tum
proliferating membrane of hydatid cysts, and sometimes in leucocytes. It appears to be associated with activity in the cells which contain it. May it not be the case that it is stored up by the liver cells when it, or some forerunner of it, reaches them from the food, as a fuel for their own activity which is evidently great and manifold, rather than as a reserve upon which the body at large may draw? Pavy's researches seem to show that the blood of the hepatic vein is no richer in sugar than that of the rest of the blood instead of containing more sugar as it should do if the liver were constantly furnishing sugar for the use of the body cells elsewhere. In short, the function of the liver as normally a distributer of sugar to the rest of the body is at present an unverified hypothesis.

Post-mortem examination of persons dead from diabetes reveals *two main changes in the liver. In a certain* proportion of cases this organ is found fatty. Thus many years ago Mead considered a "steatomatous" condition characteristic of the liver in diabetes and this phenomenon has often been noted since. But it is not invariable; indeed, it is rather the exception than the rule to find it present. In a majority of cases the liver is slightly enlarged, firm in consistency, and hyperæmic. The general impression derived from a consideration of these features is that the liver is an organ which has been working hard; the appearances do not suggest a morbid state. A peculiar lesion of the liver in diabetes has, indeed, been described by Fischer who found in a case of this disease appearances suggesting a growth of fine fibrous tissue running between the cells and columns of cells; this was quite unlike ordinary cirrhosis, either of the fine or the coarse variety, being only visible microscopically and then only on careful observation. After finding this appearance in one case of diabetes Fischer examined all the sections of liver tissue which he had by him and found among them two specimens presenting the same peculiarity. On referring to the notes of the cases from which they were taken he discovered that both of these specimens were from cases of diabetes. In one case which I examined the liver cells in certain places stained badly and here and there I noticed an appearance in these degenerate areas suggestive of the condition recorded by Fischer; it gave the impression of a cement substance between the cells which had somehow been rendered visible. So far this discovery has not been confirmed by other observers and
in any way with the causation c
case there was no sign of injury

Frogs deprived of their livers do not show any sugar in the urine as a result of the operation; nor do they exhibit diminished tolerance for carbohydrate food, with the doubtful exception of lævulose which is said to appear in the urine if administered to the animals. Indeed, the idea that it is some failure in the functions of the liver which is the cause of diabetes is negatived by the fact that in acute yellow atrophy of this organ there is no excess of sugar in the blood or urine; nor is cirrhosis of the liver, however advanced, usually accompanied by glycosuria. Strauss in 38 cases of disease of the liver found alimentary glycosuria as a consequence of the administration of 100 grammes of dextrose in only two instances.

If, then, the liver be at fault its influence must be exerted in the direction of over-activity rather than in that of defective action. We cannot at once exclude the possibility of such a mode of causation. Nevertheless, we must bear in mind that in one form of diabetes, that known as *diabète bronzé*, to which I shall refer again later, there is advanced cirrhosis of the liver; and in one case of ordinary diabetes I myself found a very advanced and apparently active cirrhosis present. Out of 12 necropsies on diabetic subjects which I collected from our post-mortem registers, cirrhosis of the liver was present in two instances. Such a condition is hardly compatible with an excess of function. Further, if we attempt to apply the conception of an over-activity of the liver as an explanation of the cardinal facts of diabetes we shall find it inadequate. It is possible, indeed, to explain the existence of an alimentary glycosuria on the basis of a continual building up and discharge of glycogen by the liver; but it seems quite impossible to harmonise this conception with the internal formation of sugar from the body tissues, to which I have already alluded as the most characteristic feature of the disease, except on the hypothesis that the liver manufactures some poison which causes
down of the cells. This has not, so far as I
suggested. Naunyn's observation that acid
does not occur in cases of hepatic diabetes (glycosuria?) seems to support the view that this organ is not the seat of the primary lesion in true diabetes mellitus, since this acid poisoning is one of the most characteristic phenomena of diabetes.

The kidneys.—Attempts to explain diabetes as a disease of the kidneys have been made from the earliest times, as was indeed natural seeing the prominence of diuresis *as a feature of the malady. Galen explained diabetes* as owing to the kidneys attracting the urine to themselves through the vena cava, though he elsewhere explains the disease as involving a fundamental defect of metabolism (*νέκρωσις ἀμφοτέρων τῶν δυναμέων ἀλλοιώσεως τε καὶ καθελκτικῆς*). Some of the writers of the eighteenth century also favoured a renal explanation of the disease, speaking of a "laxity of the urinary passages." It is curious that one of the *supporters of this latter crude view of the pathology of* diabetes should criticise Galen's hypothesis as involving "fertility of imagination rather than solidity of reason."[2] When we examine the actual morbid anatomy of the kidneys in diabetes we find a curiously close resemblance to the conditions met with in the liver. In the majority of cases the kidneys are large, firm, and somewhat hyperæmic; they suggest, as was the case with the liver, that they have worked their hardest to compensate the condition existing in the blood, rather than that they are the organs primarily at fault. In other cases the renal cells exhibit some fatty accumulation, such as is also seen at times in the liver, or they may contain glycogen granules. In still other instances the epithelium of the tubules has undergone hyaline degeneration. In a recent fatal case of diabetes terminating in coma, in which I examined the kidneys along with the other organs—the material being kindly placed at my disposal by Mr. P. L. Daniel, pathologist to Charing Cross Hospital—I found that practically the whole of the tubal epithelium was in a state resembling coagulation necrosis; the cells refused to take on any stain and even the nuclei could not be discovered by any staining methods. The glomeruli appeared to have escaped the morbid process to some extent and the cells and nuclei of the intertubular connective tissue were readily stained and appeared quite normal. No thrombosis of the renal vessels was found to account for this condition which must be looked upon as a result of the intoxication existing in the disease. It is natural to wonder whether the condition of the kidneys can have had anything to do with the coma with which the case terminated. It seems not impossible that in some instances at any rate, coma may be brought about as the result of a vicious circle, the kidneys being first injured by the toxic substances present in the blood which it is their function to eliminate; and this injury finally resulting in an inability to carry on their excretory function, in consequence of which failure a rapid accumulation of the poisons occurs in the system with speedily fatal issue. The sudden onset of coma appears to demand some cause of rapid accumulation of the poisons which are at work and this may perhaps be more easily explained as the result of diminished excretion than by a suddenly increased formation. The occurrence of albuminuria towards the end of cases of diabetes appears to point to the supervention of renal disease as a not very infrequent complication.

So far as the sugar present in the urine is concerned it seems satisfactorily established that the kidneys merely eliminate from the blood the sugar which is poured into it from elsewhere. There would seem to be present normally in the urine a percentage of sugar equal to that existing in the blood. One set of phenomena, and one only, has been pointed to as lending support to the theory of a renal diabetes. These phenomena are those which are seen as the result of poisoning with the substance called phloridzin. The effect of administering this drug to animals is to produce a condition apparently exactly resembling diabetes, the condition lasting as long as the drug is continued but ceasing on its discontinuance. Not only does sugar appear in the urine but the acid intoxication characteristic of severe diabetes in human subjects is induced and death may occur in a condition resembling diabetic coma. Phloridzin is a glucoside derived from the thorn-apple and it might be suggested that it was itself converted into sugar; but, as a matter of fact, a very small dose of the substance may give rise to the excretion of many times its own weight of sugar. It is generally supposed that the glycosuria of phloridzin poisoning is produced by an increase in the permeability of the renal epithelium, so that it allows an increased quantity of sugar to pass through it. In proof of this explanation is adduced the effect of the administration of the drug to birds. In these an increased sugar content can be produced in the blood, without any sugar appearing in the urine, owing to the power possessed by the avian kidney of retaining sugar and refusing to allow its passage. If phloridzin be given to a bird in such a condition sugar immediately appears in the urine, apparently owing to injury to the renal epithelium. Other substances which injure this structure may produce the same results. The occasional glycosuria seen in cases of Bright's disease has been attributed to a similar injury to the cells of the kidneys; but it appears, on the other hand, that the existence of renal disease—either natural or experimental—may prevent the appearance of glycosuria in phloridzin poisoning (Klemperer, Richter). It is further clear that though injury to the renal epithelium may account for some of the glycosuria seen in phloridzin poisoning it cannot do so for all, since a much larger amount of sugar issues in the urine than normally exists in the blood. The drug must itself give rise to some increased formation of sugar. The acid intoxication coexisting must also be accounted for. It is noteworthy that observers differ in their findings as to the amount of sugar present in the blood in animals poisoned with phloridzin, some finding a condition of glychæmia, others a normal amount of sugar, others again a variable quantity which may exceed or fall short of the normal. It is also difficult to explain the fact that phloridzin may produce glycosuria if tranfused through a kidney locally. Pavy, Brodie, and Siau consider that phloridzin acts upon some substance already existing in the blood and converts it into sugar. It would seem necessary to suppose that it produces excess of this intermediate substance in the blood by its own action.

---

[2] Anonymous Treatise, 1745.

The administration of phloridzin is followed by intense fatty change in the liver which may be compared with the fatty condition sometimes seen in cases of diabetes. Some very interesting experiments were made by Rosenfeld to determine the source of this fat. By starving animals (dogs) for some time it is possible to get rid of practically all the stores of fat existing in their bodies. If now such starved animals be fed on some fat of a different kind from that normally present in their tissues they store up the new form of fat instead of the ordinary kind and it is possible by chemical tests to demonstrate the difference. If then to an animal thus treated, containing abnormal fat in its adipose tissues, a course of phloridzin be given and the fat in the liver resulting from the treatment be analysed, it is found that the fat of this organ consists of the extraneous fat, not of normal canine fat. The clear inference is that the fat found in the liver is not a fatty degeneration in the ordinary sense, in which the fat is derived, or is supposed to be derived, from breaking-down of the substance of the liver cells, but that the fat is brought to the liver by the blood and is merely ingested by the cells from the fluids surrounding them. As a result of Rosenfeld's experiments, which have been adequately confirmed by other observers, considerable doubt is thrown on the commonly accepted views on fatty degeneration. So far no connexion has apparently been drawn between the fatty condition of the liver and the glycosuria, but it seems not impossible that such a connexion does exist. I shall hope to allude to this side of the question later in my third lecture. In any case the condition produced by phloridzin is almost exactly the same as that seen in diabetes, in respect to the condition of the urine, to the acid intoxication, and to the fatty state of the liver; and arguments drawn from its peculiar features may be applied to the human disease.

Nervous system.—The connexion of the nervous system with diabetes has already been alluded to in so far as nervous influences may be effective in determining the onset of the disease. It seems, however, rather the exception than the rule to find any recognisable lesions of this system after death in cases of true diabetes. On the other hand, patients dying from cerebral lesions may exhibit glycosuria up to the time of their deaths. In a certain number of cases classed as diabetes, tumours or other affections of the medulla have been found post mortem. It is at least open to question whether these cases should not rather be described as instances of persistent glycosuria than of diabetes, death being assignable to the cerebral lesion rather than to any nutritional disturbance. Apart from such lesions the changes met with in both brain and spinal cord are most easily explained as secondary changes due to the general wasting and intoxication; such are the atrophy of the convolutions, the widening of the perivascular spaces, the local cysts, the œdema of the membranes, and the dilatation of the ventricles and iter (Dickinson). The localised hæmorrhages sometimes found are analogous to the retinal hæmorrhages characteristic of diabetes and the atrophy and sclerosis of some of the columns of the spinal cord are comparable with the somewhat similar condition which occurs in pernicious anæmia and are due either to malnutrition or to intoxication. The neuritis which may be met with in the peripheral nerves is also almost certainly due to the general intoxication and is comparable with the neuritis produced by alcohol, a substance very closely allied to sugar, by fermentation of which it is generally produced, but it may equally be due to some secondary intoxication or infection rendered possible by the debilitated state of the tissue. Changes in the sympathetic system are also probably secondary and not causal.

The stomach.—The causation of diabetes was assigned to the stomach by some of the older writers. Thus, Lister placed the defect in this organ and Rollo, who wrote a careful account of the malady, attributed it to excess of gastric fluid, along with some alteration in the quality of the secretion, by which sugar was formed in the organ. There is, however, little or nothing to connect diabetes with gastric disorders so far as morbid anatomy is concerned. It is true that Joneways and Ortel described a case associated with acute gastritis, but this was almost certainly secondary and due to a terminal infection. In most cases the stomach appears to do its work admirably as is proved by the absence of digestive disturbances in spite of the large amounts of food taken. A form of "dyspeptic glycosuria" has, however, been described by Robin in which the sugar appears in the urine only during digestion. The stomach is found dilated and there is hyper-acidity of the gastric juice; the liver may be slightly enlarged. The patients suffer from neurasthenia and there is phosphaturia along with the glycosuria. According to Robin the condition may pass into true diabetes. It seems more natural to connect the condition with the neurotic condition of the sufferers, since diabetes, or at least glycosuria, is not infrequently noticed to accompany neurasthenia, than to suppose any special form of the disease.

The skin.—Apart from the various secondary lesions of the skin due to invasion of pyogenic organisms, such as boils and carbuncles and the local effects of saccharine urine or its decomposition products seen in the neighbourhood of the urethral orifice, there are two conditions of the skin which are said to be specially connected with diabetes mellitus. These are psoriasis and xanthoma. The nature of neither of these is fully understood. Xanthoma appears to be due to a special form of fatty degeneration of the cells of the corium and may, perhaps, be brought into line with the other instances of fatty change already alluded to. Psoriasis has been variously attributed to the presence of an undiscovered organism—as suggested by the ring-shaped lesions of the disease—and to a toxin or dyscrasia. If the former explanation be true—but so far there is no proof of such a cause—its association with diabetes might be similar to that of the pyogenic affections. If, on the other hand, it is toxic it may be due to the same cause which produces the glycosuria or may be produced by the presence in the skin of sugar or some allied substance. It is noteworthy that among 25 cases of psoriasis Nagelschmidt found eight instances of alimentary glycosuria; whereas among patients suffering from other diseases of the skin who happened to be in hospital at the same time no instance of this condition occurred. Pick, however, denies that alimentary glycosuria is frequently found in patients suffering from psoriasis. The question therefore seems still undecided It has however, very little bearing on the nature and manifestations of true diabetes

ABSTRACT OF

The Hunterian Lectures

ON

THE DISSEMINATION OF MAMMARY CARCINOMA.

Delivered before the Royal College of Surgeons of England on March 13th 15th and 17th, 1905,

BY W SAMPSON HANDLEY, M S, M D LOND, F R C S ENG,

HUNTERIAN PROFESSOR SURGEON TO OUT-PATIENTS SAMARITAN FREE HOSPITAL RICHARD HOLLINS CANCER RESEARCH SCHOLAR THE MIDDLESEX HOSPITAL

LECTURE I

Delivered on March 13th

MR PRESIDENT AND GENTLEMEN —The subject on which I have the honour to address you—the dissemination of a typical and frequent variety of cancer—is a minor one as compared with the great problems of its cause and cure Nevertheless so long as early and radical operation remains the only cure for cancer an accurate knowledge of the paths of dissemination is of the first importance If my treatment of the subject seems to you inadequate I may fairly plead its difficulty and complexity For the phenomena of metastasis are so complicated that they appear at first sight to be governed rather by chance than by law My lectures are based on work carried out in the cancer research laboratories of the Middlesex Hospital during the years 1903 04 My warmest thanks are owing to the director of the laboratories, Dr W S Lazarus Barlow for his candid and friendly criticism and for advice on difficult points To my colleagues also, especially to Mr W E Hillier, Mr W G Taylor and Dr H A Colwell and to Dr P Campiche my best thanks are due for obtaining for me material from the post mortem room when surgical avocations forbade me to visit it

The subject of cancerous dissemination is in a somewhat hazy and indeterminate condition Invasion of the axillary glands is universally admitted to be an embolic process On the subject of regional dissemination there are two schools of opinion While certain authors believe that invasion of the pectoral lymphatic plexus occurs by direct cancerous growth along the vessels others maintain that cancer cells are swept by the lymph stream through the vessels of the pectoral plexus, and that metastases arise from their casual arrest at isolated points As regards metastases in the internal viscera or at distant points in the parietes (e g, in the femur), there appears to be only one definite theory of causation—that known as the embolic theory Some writers doubtful, perhaps, of the validity of the embolic theory, ignore the subject entirely Before

the ground by considering

d dissemination

THE EMBOLIC THEORY

The embolic theory[1] presumes that particles derived from the primary growth obtain access to the blood and are carried by the force of the circulation to remote districts, where their cells proliferate and produce secondary nodules There can be no doubt that cancer cells frequently obtain access to the blood, either by passing into it along the thoracic duct or by invading the small veins in the vicinity of the primary growth Goldmann has drawn especial attention to the latter form of invasion Mr Stephen Paget,[2] however, showed that in the simple form stated above the embolic theory is untenable He pointed out that embolism is necessarily an impartial process to which all the organs are liable But the distribution of cancerous metastases in the various organs is by no means impartial Some organs are very frequently invaded others only rarely Hence it was necessary to assume that certain organs form a favourable nidus for the emboli which lodge in them while in other organs the embolised particles are destroyed or rendered incapable of growth Among the salient facts brought forward by Paget in support of this view that tissue predisposition determines the success of embolic invasion were the following Of 735 cases of cancer of the breast while the liver showed cancer in 241 only 17 had cancer of the spleen On the other hand in 340 cases of pyæmia abscess of the liver occurred 66 times and of the spleen no fewer than 39 times Again, since cancerous particles reaching the blood must pass through the lungs to gain the systemic circulation it appeared remarkable that these organs showed cancer in only 70 out of 735 cases of cancer of the breast which Paget collected He further showed that each variety of primary growth has its own special metastatic geography For instance while bone deposits are frequent in cancer of the breast and of the thyroid Gussenbauer and von Winiwarter found not a single instance among 903 cases of cancer of the stomach So that the tissue predisposition of the different organs must be assumed to vary according to the particular viscus in which the carcinoma originates Proceeding in his acute analysis of the embolic theory Paget showed that certain bones are habitually affected in cancer of the breast while others invariably escape In the face of this difficulty he was driven to assume that tissue predisposition to cancer is a variable factor as between different parts of the skeleton—that while the humerus for instance, possesses it in a high degree the radius equally subject to cancerous embolism possesses a natural immunity to carcinoma The embolic hypothesis seems by such a supposition to be strained to breaking point There can be no doubt that in certain rare cases of carcinoma embolism by way of the blood stream does occur as a process effective in causing metastases Such a case for example is that of R Voll in which a gastric carcinoma after invading the liver had produced cancerous pulmonary embolism Daughter nodules were found in the kidneys in the brain and upon atheromatous ulcers in the thoracic aorta But as a general explanation of metastasis the embolic theory is negatived by a study of metastatic distribution

Among more recent contributions to the subject of invasion of the blood by carcinoma the most valuable is that of M B Schmidt[3] whose work has not yet received, in this country at any rate the attention due to its importance Schmidt examined the condition of the lungs in 41 cases of carcinoma Rejecting cases where the lungs were healthy or had primarily been invaded by the lymphatics or where the primary mode of invasion was uncertain he obtained 15 cases showing cancerous embolism of the small pulmonary arteries. In all these cases the primary growth was situated in the abdomen. Schmidt's general conclusions had better be given in a translation of his own words. It will be seen that he remains an advocate of the embolic theory. "In carcinoma of abdominal organs cancerous embolism of the small arteries of the lungs occurs with unlooked-for frequency and often repeatedly. Only a small proportion of these emboli give rise to metastatic tumours or break through the arterial wall into the perivascular lymphatics. Most of them are either destroyed by organisation of their ensheathing thrombus, or while retaining the power of growth are encapsuled and rendered harmless. They may, however, push forward through the organising thrombus which surrounds them, into the capillaries and small pulmonary veins, and may so give rise to growths in the course of the systemic circulation. All this may happen while to the naked eye the lung remains unaltered." Schmidt's work is a convincing demonstration of the frequency of blood invasion, at any rate in carcinoma of the abdominal cavity. It is worth noting that his 41 cases included two of cancer of the breast, and that in neither of these was he able to demonstrate pulmonary embolism.

---

[1] A full statement of the embolic theory and of its difficulties will be found in Mr W Roger Williams's Diseases of the Breast 1894 p 207 Mr A M Sheild (Diseases of the Breast 1898 p 455) also appears to accept the embolic theory

[2] Stephen Paget The Distribution of the Secondary Growths in Cancer of the Breast THE LANCET March 23rd 1889

[3] M B Schmidt Die Verbreitungswege der Karzinome Jena 1903

In order, however, to establish the embolic theory it is necessary to show that this blood invasion is effective. I would suggest to you that this is rarely the case, that as a rule cancerous epithelium which reaches the blood stream is either destroyed or rendered incapable of growth. If the tissues were arranged in order of specific resistance to cancer, it seems probable that, next perhaps to cartilage, blood would take the highest place. Among Schmidt's 15 cases of cancerous pulmonary embolism only three showed secondary deposits in the lungs visible to the naked eye. In two of these cases miliary nodules were present, while in the third a solitary nodule was present in one lung. Even in the lungs, then, the chances against the macroscopic success of a cancerous invasion by way of the blood appear to be 5 to 1. It may indeed be said that in the twelve cases where naked-eye metastases failed to develop the invasion was recent and would have ultimately succeeded. Such an argument defeats itself, for if blood invasion only occurs at the doors of the post-mortem room, it evidently cannot be an important factor in dissemination.

Schmidt's work shows why cancerous epithelium as a rule fails to colonise the blood stream. The cancer cells excite thrombosis and the thrombus as it organises and contracts destroys them. Goldmann found that thrombosis might even precede the actual cancerous invasion of a vein. He also showed that invasion of the veins near the primary growth might occur in cases which were found post mortem to be entirely free from metastases. Schmidt found thrombotic material round some or all of the cancerous emboli in the lungs in 14 out of 15 cases and round all of them in seven cases. He was able to trace all the stages in the destruction of cancerous emboli of the lungs. In one case particularly there were numerous arterial thrombi apparently the result of cancerous embolism, though at only one point were recognisable cancer cells still present within a thrombus. In the remaining case of the 15 all the cancerous emboli were devoid of thrombotic covering, yet even in this case the only other visceral metastases occurred in the liver and were therefore the cause and not the consequence of the cancerous invasion of the lungs.

In showing that cancer cells in blood excite thrombosis and that the thrombus as it organises usually destroys or renders them harmless, Goldmann and Schmidt seem to have established a fact of first-rate importance and one strongly opposed to the embolic theory. Cancer in lymphatic vessels, as far as I have seen, excites no such thrombosis. Hence it is, no doubt, that although carcinoma often obtains access to the blood almost as early as to the lymph, its dissemination takes place almost entirely by the lymphatics and not by the blood-vessels. It is a significant fact that chorion epithelioma, the only carcinoma certainly known to spread habitually by the blood, ends oftener in spontaneous cure than does any other form of carcinoma. In a series of 188 cases of chorion epithelioma Teacher[4] records four instances of apparently complete recovery following an incomplete operation and eight other cases in which, though hæmoptysis indicated lung metastases, removal of the uterus was successful in restoring the patient to health. It would be easy to adduce other arguments against the embolic theory. I find, for instance, that in 12 per cent. of cases of cancer of the breast the abdomen is invaded by growth, while the thorax, the channel by which on this theory cancer reaches the abdomen, remains free; and that the distal halves of the limbs, where non-cancerous embolism so frequently occurs, are not liable to secondary deposits in cancer of the breast. The theory can, however, only be effectively attacked by constructive criticism. I venture to think that the facts can be better explained on the hypothesis of centrifugal lymphatic permeation which I propose to lay before you.

External (Parietal) and Internal (Visceral) Dissemination.

The secondary deposits which occur in cancer of the breast may be considered under two headings: first, those which occur in the parietes and in the limbs—that is to say, in the skin, the subcutaneous tissue, the deep fascia, the muscles, and the bones; secondly, those which occur within the thoracic or abdominal cavities or in the central nervous system. This anatomical division of the metastases corresponds to the two forms of dissemination, parietal and visceral, which occur in cancer of the breast. They usually occur in combination, but that the *distinction is a natural and not an artificial one* is clearly proved by such cases as those of Arnott[5] and of Walther[6] and by a case of which a model exists in the museum of St. Thomas's Hospital, a photograph of which I shall show you. In these instances there were multiple and widespread metastases in the bones or in the bones and subcutaneous tissues, while the internal organs were free from cancer. The occurrence of such cases—extremely difficult to explain on the embolic theory—suggests that visceral dissemination is a secondary and not invariable consequence of parietal dissemination and that the latter should be the primary object of study. The remainder of this lecture will be devoted to a clinical and statistical study of parietal dissemination.

Parietal Dissemination a Centrifugal Process.

When a few scattered nodules of cancer are found in the skin near a cancer of the breast, or when the adjacent ribs or the sternum show cancerous nodules, no difficulty is felt in attributing these to local lymphatic spread. But when subcutaneous nodules are present over the greater part of the surface of the body, or when distant bones such as the femora or the cranium are attacked, the hypothesis of centrifugal lymphatic spread is abandoned for that of embolic blood invasion. It appears to me that there is no sufficient reason for this change of attitude. That centrifugal spread may annex by continuity a very large area round a carcinoma is convincingly shown by cases of cancer *en cuirasse.* In a recent paper[7] I have brought forward *primâ facie* evidence to show that nearly all bone and skin metastases, no matter how remote from the primary growth, are due to centrifugal spread by continuity. The facts may here be briefly summarised.

The Skin and Subcutaneous Fat.

Velpeau's statement that subcutaneous nodules make their first appearance in the near neighbourhood of the primary growth has never been controverted. And in carefully recorded cases, such as those of Mr. Stanley Boyd[8] or of Dr. Byrom Bramwell,[9] it will be found that as the case progresses they appear at points more and more remote from the primary growth. Fig. 55 in Sheild's well-known book depicts a middle stage of the process of nodule formation. You see the nodules involving a considerable circular area round the growth. They have spread rather more in a vertical than in a horizontal direction and this appears to be a general rule. The next case, that of Dr. H. D. Rolleston,[10] shows extremely numerous nodules. They have indeed involved the greater part of the surface of the body and Rolleston ascribed them to invasion by the blood stream. But the point I would emphasise is that their concentric arrangement round the primary focus is still preserved. The arms beyond the deltoid insertion and the lower limbs beyond the upper point of trisection of the thigh are quite free from nodules. This is not a peculiarity of this particular case. In two cases I have myself observed, in Bramwell's case, and in one or two among the Middlesex records, the distal portions of the limbs have been the only skin areas free from nodules. Thus the area involved in the most extreme recorded cases is only an extension of the circle of invasion so clearly shown in Sheild's case. It will be found, too, that as a general rule the nodules near the primary growth are the largest and those farther away are smaller in size and less closely adherent to the skin. In some rare cases, as in one recently at the Middlesex Hospital of which I show you a photograph, skin nodules may ulcerate. It is noticeable that the ulceration is most marked in the immediate neighbourhood of the primary growth. These facts all support the centrifugal hypothesis, since they show that the oldest nodules lie near the centre of the invaded area of skin, the most recent ones near its periphery.

THE SKELETON.

The annexed table summarises the experience of the Middlesex Hospital for 30 years with respect to bone deposits secondary to cancer of the breast.

TABLE I.—*Showing the Frequency of Cancerous Deposit or Spontaneous Fracture in 529 Cases of Mammary Cancer at the Middlesex Hospital, 1872-1901.*

	Bone.	Number of cases.	Percentage of total.
Bones lying wholly or partially within the area liable to subcutaneous nodules.	Sternum	30	9·0
	Ribs	28	8·0
	Clavicle	5	1·5
	Spine	12	3·6
	Cranial bones	9	2·7
	Scapula	1	0·3
	Femur	14	4·2
	Os innominatum	0	0·0
	Humerus	9	2·7
Bones lying beyond the area liable to subcutaneous nodules.	Radius	0	0·0
	Ulna	0	0·0
	Tibia	1	0·3
	Fibula	0	0·0
	Patella	1	0·3
	Bones of hand	1	0·3
	Bones of foot	0	0·0

The post-mortem examination of the skeleton is nearly always fragmentary and incomplete and so consequently are the records of osseous metastases. They are trustworthy only for those bones in which extensive cancer usually causes a fracture which attracts the attention of the pathologist. The escape of certain flat bones from cancerous deposit, which the table indicates, is therefore apparent only, while the escape of certain of the long bones from cancer—bones necessarily liable from their shape to spontaneous fracture—must represent a real fact. Making allowances for the fallacies inherent in this table it will be found [illegible] ch point strongly to cer[illegible] on the embolic theory [illegible] erous metastasis increases with its proximity to the site of primary growth. 2. The bones distal to the knee and elbow escape invasion except in the rarest instances. [illegible] which Mr. Sha[illegible] del in the Mus[illegible] second of thes[illegible] of bone deposits secondary to mammary carcinoma which I have been able to find. There were no visceral deposits. The skeleton had undergone great distortion. The sternum and ribs have sunk until the former almost appears to touch the vertebral column, the whole thorax being flattened out transversely. The pelvis exhibits a precisely similar modification. The right humerus and both femora have undergone fracture. Yet as you can see the legs and forearms have entirely escaped deformity. Thus bone metastases occur only in bones which lie wholly or partially within the area liable to subcutaneous nodules. The reason why the distal halves of the limbs nearly always escape metastases in cancer of the breast is that by the time the parietal tissues have been invaded as far as the knee and the elbow, if not earlier, death intervenes. Rare exceptions may, of course, occur, but only one such exception was found in the records of the Middlesex Hospital for 30 years.

We may now inquire more particularly at what exact point the long bones of the limbs are usually invaded. It has been already stated that *only the humerus and the* femur are subject to metastases and the scope of our inquiry is therefore limited to those two bones.

THE FEMUR.

Among 14 cases of bone deposit or spontaneous fracture in one or both femora there were three in which the bone was involved more or less along its whole length. In two of these three cases it is stated that the process was most *advanced in the upper two-thirds of the bone. In each* of the other 11 cases the pathological condition was present in the upper third of the bone, most often about two inches below the base of the great trochanter. This point of maximum incidence does not coincide with the usual positions of senile fracture of the femur nor with the point of entry of the nutrient artery. The femur appears to be invariably invaded near the base of the great trochanter or along the upper part of the gluteal ridge. Among the eight cases of unilateral cancer of the femur in which it is stated in which breast the primary growth was situated, the fracture was on the same side in six instances and on the opposite side in only two. This preference seems inconsistent with the embolic theory while perfectly consistent with that of centrifugal spread, which would reach the femur of the same side before it had spread sufficiently far to attack the opposite femur.

THE HUMERUS.

In ten cases secondary deposit or spontaneous fracture occurred in one or both of the humeri. Of the eight separate bones in which fracture occurred it was found at the middle point in four and at varying points through the lower third, the thinnest part of the bone, in the remaining four. The seat of election for cancerous fracture of the humerus is therefore at the deltoid insertion. The infrequency of cancerous deposit in the humerus is probably apparent only. The arm is bound to the side by a mass of axillary growth and splinted by solid œdema. Thus it escapes spontaneous fracture and there is nothing at the necropsy to attract the pathologist's attention. Fracture of the humerus occurred on the same side as the growth in only three instances, while in four cases the opposite humerus broke.

CENTRIFUGAL SPREAD AS MANIFESTED IN THE SEAT OF ELECTION OF CANCER OF THE FEMUR AND OF THE HUMERUS.

The almost exclusive preference of secondary carcinoma for a point in the femur at or just below the great trochanter and its less marked preference for the middle point of the humerus seems at first sight to offer no particular support either to the embolic theory or to that of centrifugal spread. On consideration, however, it will be seen that in both bones the area invaded is the subcutaneous area which lies nearest to the trunk. If cancer spreads centrifugally from the primary focus along the deep fascia this is exactly what would be likely to happen. It will be shown later that the parietal growing edge of a cancer of the breast does actually lie in this layer. We have now obtained clear indications that the cancerous areas of the parietes in successive stages of the case are circles of ever-increasing radius concentred on the primary neoplasm.

PRIMARY EXTENSION IN THE DEEP FASCIA INDICATED BY OPERATION RESULTS.

The secondary deposits in the skin and the bones appear scattered and isolated; it is therefore improbable that parietal dissemination takes place *along* these layers. Since the main lymphatic plexus is situated upon, or close to, the deep fascia it is probable that parietal extension takes place primarily in the plane of the deep fascia and that nodules in the skin, the muscles, and the bones are local efflorescences from the cancerous *fascial* lymphatic plexus. Valuable evidence on this point may be obtained by comparing the results of two operators, one of whom removes a moderate area of skin and undermining the flaps excises the deep fascia much more widely than the skin. The other removes a wider area of skin but does not undermine the flaps and therefore removes a smaller area of deep fascia. Table II. shows the comparative results obtained.

TABLE II.—*Showing the Comparative Results of Very Wide Removal (a) of Skin; and (b) of Deep Fascia in Breast Cancer.*

Operator.	Number of cases.	Practice as regards removing.		Percentage of successes.	Percentage of external recurrences.	Situation of external recurrences.		
		Skin.	Deep fascia.			*Local* recurrence, position unknown.	Pectoral muscles or ribs.	Surrounding skin.
				%	%	%	%	%
Halsted.	50	Very wide removal.	Removal coterminous with that of skin, except towards axilla, where it is greater.	41	21	—	6	16
Watson Cheyne.	61 first series.	Wide removal.	Very wide removal.	Upwards of 50.	18	5	6·5	6·5

This table shows that the operator who removes the smaller area of skin yet has a lower percentage of skin recurrences, a result which is unintelligible if cancer spreads along the skin. The operator who removes the smaller area of deep fascia has a higher percentage of skin recurrences, in spite of his wider removal of skin, because growth subsequently extends to the skin from the infected area of the deep fascia which has been left behind.

THE LYMPHATIC ANATOMY OF THE PARIETES.

[The lecturer next reviewed the lymphatic anatomy of the parietes. He showed that the lymphatics of the skin did not, according to Sappey nor according to his own observations, form beneath the dermis the deep cutaneous plexus described by Arnold. He also showed that probably the main stream of lymph from the breast passes by the retromammary lymphatics to the pectoral fascia and thence indirectly to the axillary glands. He continued :]

The pectoral lymphatic plexus is often spoken of as if it were an anatomical entity. It is in reality merely a conventional subdivision of the deep fascial lymphatic plexus, a network of intercommunicating channels which invests the entire body. This great plexus is divisible by the median plane of the body and by horizontal planes passing through the clavicle and through the umbilicus into six catchment-areas, three on either side, draining respectively into the cervical, the axillary, and the inguinal glands. Within each area a special set of trunk lymphatics arises from the plexus and converges on the corresponding set of glands. The line, or rather zone, separating adjacent areas may be called the lymphatic water parting and is anatomically a zone of narrow tortuous channels nowhere traversed by trunk lymphatics—a region consequently where the lymph stream is at its feeblest and where even very fine particles are liable to be arrested. The general idea, then, which we have obtained of the parietal lymphatic system is that of a vast horizontal network of fine channels, coextensive with the surface of the body and receiving above numberless fine vertical tributaries, which convey to it the lymph from the skin and its appendages. Among the latter we must include the breast. From this great plexus the lymph is conveyed by six sets of lymphatic trunks, each draining a definite area, to the cervical, axillary, or inguinal glands. On its deep aspect the fascial plexus communicates by fine anastomotic vessels with the muscular and periosteal lymphatics. We are now in a position to trace the advance of carcinoma along the ramifications of the great parietal lymphatic plexus. The subject may be divided as follows: (1) dissemination within the limits of the breast; (2) invasion of the underlying pectoral fascia; (3) embolism of the axillary glands; (4) retrograde embolism produced by a reflux lymph stream; and (5) centrifugal lymphatic permeation.

DISSEMINATION WITHIN THE LIMITS OF THE BREAST.

Much of the literature of cancer of the breast centres on this subject. Since I can add nothing to the valuable and well-known work of Langhans, of Heidenhain, of Stiles, and of many subsequent authors on this subject, I do not propose to deal with it. Langhans was the first to observe that the small lymphatics of the breast are invaded early and widely far beyond the infiltrating edge of the primary growth. It remains, however, still uncertain whether this lymphatic invasion is embolic or proceeds by continuous growth along the vessels. Stiles,[11] who examined over 100 breasts removed by operation, shared the embolic view of Langhans. My investigations in the extra-mammary tissues, where the conditions of observation are perhaps more favourable, show continuous growth of cancer along the lymphatics (Lecture II.), and it seems unlikely that the mode of spread within the breast is by a different method.

EXTENSION OF GROWTH TO THE PECTORAL FASCIA.

Heidenhain,[12] in 12 out of 18 cases examined, found cancerous lymphatics running from the breast to the pectoral fascia. His observations showed that the cancer generally advanced along these vessels, and along those of the pectoral lymphatic plexus, by a process of continuous growth, less often by embolism. It is an important fact that cancerous lymphatics may be found in the pectoral fascia before the growth has become adherent to the muscle, an observation which I was able to confirm in a recent case. Thus in an early stage, prior to adhesion to the skin and even before adhesion to the pectoral fascia, an area of the deep fascial (pectoral) lymphatic plexus which underlies the growth shows cancer-filled lymphatics. I shall be able to show that the parietal metastases of breast cancer are especially frequent and widespread, not on account of any special cancerous proclivity of the skin in the subjects of breast cancer but because of the intimate connexion which Heidenhain proved to exist between the lymphatics of the breast and those of the great fascial plexus.

EMBOLISM OF THE AXILLARY GLANDS.

It is probable that embolic invasion of the axillary glands cannot occur until microscopic invasion of the pectoral fascia has taken place. Embolism of the axillary glands is probably secondary to the growth of cancer along the meshes of the pectoral lymphatic plexus which Heidenhain observed. As soon as cancer cells intrude from the smaller vessels into a trunk lymphatic they are swept by the stream to the axillary glands. After long delay they penetrate these glands and the supraclavicular glands and so attain the blood stream. The route we have been tracing is usually regarded as the main avenue of dissemination. So, no doubt, it would be but for one factor—the destructive action of the blood on cancerous epithelium which was demonstrated by Schmidt. The peculiarities of metastatic distribution show that cancer cells which gain access to the blood are reduced to impotence.

RETROGRADE LYMPHATIC EMBOLISM.

There is, however, another route by which dissemination might occur. As soon as the lymphatic glands are obstructed by growth a reflux lymph stream must pass across the middle line to the opposite axillary glands, upwards to the cervical, or downwards to the inguinal glands. Very great stress has by some authors been laid on this factor in dissemination. But on account of the valves it cannot take place to any extent in trunk lymphatics. Moreover, towards the periphery of each lymphatic area the trunks break up into fine plexuses. They are incapable, therefore, of conveying cancer cells to adjoining areas, unless these cancer cells can pass through networks of small lymphatic vessels. And this appears never to happen, for, as will appear in Lecture II., breast cancer shows a definite parietal growing edge without outlying embolic foci. And the opposite axillary glands, the opposite breast, or the inguinal glands, are never found to become cancerous early in the case, as should occasionally happen if cancer cells can reach them embolically from other lymphatic areas.

PERMEATION OF LYMPHATIC PLEXUSES.

We have seen that neither the direct nor the reflux lymph stream is capable of transporting cancer particles to points lying outside the lymphatic area in which the primary growth originated The direct lymph stream is filtered of its cancer cells at the first set of glands, the reflux stream is similarly filtered in the fine anastomotic plexuses through [illegible] ic areas Thus the [illegible] f *general* dissemina- [illegible] ts of the lymphatic [illegible] In whatever direction the cancer cells attempt to leave that area they find an effective filter blocking the way How to overcome the resistance thus interposed and to reach other lymphatic areas is the essential problem of dissemination In connexion with this problem I would like for a moment to draw your attention to the behaviour of porcelain filters with respect to micro organisms Mr Kenneth Goadby informs me that certain bacteria which cannot by any degree of pressure be forced through porcelain filters will nevertheless in a few days, if left within such a filter, grow through its pores and infect its outer surface It is similarly by the aid of their own proliferative power that cancer cells succeed in traversing the meshes of the lymphatic filter in which they are imprisoned It is, of course, well known that this is the mode by which cancer cells pass through lymphatic glands But this centripetal route of invasion is relatively unimportant because it leads finally to the blood where the cancerous foci usually disappear harmlessly In a precisely similar way, by actual centrifugal growth along the meshes of the lymphatic plexuses which are in relation to the primary neoplasm, cancer cells ultimately succeed in penetrating the fine anastomotic plexuses which, at the periphery of the lymphatic area concerned, bar the way into surrounding lymphatic areas To this process of actual cancerous growth along the fine lymphatic vessels I have ventured to attach the name lymphatic permeation or simply permeation It appears to me to be the master process of dissemination For whereas in attempted embolic dissemination *viâ* the glands the migrating cells are cast away in the blood, cancer cells which migrate by way of the peripheral anastomotic plexuses simply pass into the lymphatic vessels of adjoining areas without changing their conditions of life Advancing in this way, slowly and centrifugally from one lymphatic area to the next, permeation may conceivably bring about the impregnation of the entire lymphatic system with cancer, provided only that the cancer cells possess sufficient proliferative power An approximation to this condition is apparently indicated in the cases where subcutaneous nodules or bone deposits spare only the distal portions of the limbs

PERMEATION AS SEEN ROUND PLEURAL IMPLANTATION GROWTHS

In order to make clear what I mean by permeation it will be well to study a concrete instance of the process In many cases of mammary carcinoma cancer cells obtain access to the pleural cavity and, gravitating through it, implant themselves at some point on the serous surface Soon small pseudo papillomatous secondary growths are seen projecting into the pleural cavity at the point of implantation If now a piece of the pleural membrane be stripped off and held up to the light each of these growths will be seen surrounded by an opaque, slightly thickened, more or less circular area of pleura, perhaps an inch or two in diameter, which presents to close examination a network of white lines just visible to the naked eye The microscope shows that these lines are the vessels of the sub pleural lymphatic plexus filled by lines of cancer cells In the pleura and in certain other situations, under the misleading name of "lymphangitis carcinomatosa," permeation has long been recognised and described Borst[13] regards this process as peculiar to the serous membranes, the diaphragm, the lungs, and the liver, and does not describe it as playing any important part in dissemination The name "carcinomatous lymphangitis" is evidently a misnomer It would be equally correct to describe a preparation showing lymphatics injected with mercury as one of mercurial lymphangitis In both cases the process is primarily mechanical or at any rate not inflammatory The mercury and the cancer cells, under the influence of pressure, follow the lines of least resistance But since in the case of the cancer cells this driving force is an internal pressure resulting from their own proliferation it is not quite correct to speak of cancerous injection of the lymphatics, the process of permeation is rather one of tendril like cancerous growth along the lymphatics. The anastomotic plexuses which divide the lymphatic system of the body into separate areas and form effective barriers against embolic dissemination are powerless to check the advance of permeation So far as this process is concerned the whole lymphatic system is a single network of accessible channels and by its slow centrifugal extension the whole body might ultimately be impregnated by cancer cells My main task in succeeding lectures will be to describe the details of this process, to show why its importance has escaped observation, and to justify my belief that it is the master process of dissemination

---

The Lettsomian Lectures

ON

THE MENTAL DISORDERS OF DECAY.

Delivered before the Medical Society of London on Feb 6th and 20th and March 6th, 1905,

BY GEORGE H. SAVAGE, M D LOND,
F R C P LOND.,

CONSULTING PHYSICIAN TO, AND LATE LECTURER ON MENTAL DISEASES AT, GUY'S HOSPITAL

LECTURE III [1]

Delivered on March 6th

MR PRESIDENT AND GENTLEMEN,—The first group of cases I have to consider has been well called by Clouston postponed idiocy More recently we have had other names, insanity of adolescence and dementia præcox Secondly, I shall have to consider disorders of malnutrition, toxic states such as brain syphilis, and general paralysis of the insane, and, lastly, I shall have to describe true cases of senile dementia

Postponed idiocy has been called developmental and it must be remembered that the same initial mental or brain disease may lead to different exhibitions according to temperament, environment, and education Youth is not on the side of the neurotic, if in a youthful patient there is strongly marked inheritance of neurosis the danger is still greater A large number of these cases are simple in their onset There are a number of boys and a yet larger number of girls who break down at adolescence Clouston confirms my experience that the boys who break down at adolescence are less hopeful than the girls who break down under similar conditions There seems to be a definite class of individuals with a capacity to attain a certain stage, their nutritive side is all right, but as soon as the stress of sexuality comes, altruism, with love and allied emotional states, then these individuals have not the power to stand it and accordingly they break down Very many of these cases predisposed by heredity have with the onset of pubescence some other form of disturbance, and one which deserves further consideration—namely, febrile attacks I have seen patients, aged 15 or 16 years, said to be doing hysterical and stupid acts, whose friends stated that from infancy they had had every year or two a feverish attack, their temperature running up to 101°, 102°, or 103°, or even 104° F, but without any recognisable cause There seems to be a febrile condition that not infrequently ends in disturbance of the mind Then there is the subject who is predisposed by over-training, mental or muscular, or both An individual whom I have seen recently was a double Blue and a double first, and the result is dementia It is a case of overstrain and over training in a neurotic person A certain number of cases break down as a result of shock One has seen cases in which there has been a suspicion of criminal assault, and after that there have been hysterical symptoms, maniacal or hypochondriacal disorders, followed by permanent weak mindedness Undoubtedly in some of these cases there has been an assault

[1] Lectures I and II were published in THE LANCET of Feb 18th (p 409) and March 11th (p 630) 1905, respectively

TABLE I.—CASES OF FEVER AFTER MISCARRIAGE OR LABOUR AT FULL TERM.

A—CASES TERMINATING IN DEATH. *B*—CASES OF SEVERE FEVER WITH RECOVERY. *C*—CASES OF SLIGHT FEVER WITH RECOVERY.

A—Cases terminating in Death.

No.	Labour at full term or miscarriage.	Age.	Bacteriological examination of uterus.	Bacteriological examination of vaginal discharge.	Date after confinement on which bacteriological examination was made.	Onset of symptoms after confinement.	Result.	—
1	Full term, eleventh pregnancy.	—	Streptococcus (pure culture).	No examination.	During sixth week.	Fever commenced on fifth day.	Death during seventh week after delivery.	*History.*—Retained membranes; temperature 105° F. and offensive purulent discharge from the cervix (sixth week); symptoms of peritonitis and pleuritis before death. No special treatment. No examination after death.
2	Full term.	—	Streptococcus pure culture).	No examination.	On twenty-second day.	Fever commenced on seventh day.	Death.	Uterus enlarged (twenty-second day); large sub-mammary abscess (containing streptococci in pure culture).
3	Full term, sixth pregnancy.	28	Streptococcus and bacillus coli communis.	Streptococcus and bacillus coli communis.	After death (cultures taken 13 hours after death).	Fever commenced on third day.	Death on sixth day after delivery.	*History.*—High intermittent fever; "typhoid" condition and collapse. *Necropsy.*—Cultures taken from the heart blood, spleen, and peritoneal sac all showed streptococci in pure culture.
4	Miscarriage (probably after an illegal operation), third pregnancy.	23	Streptococcus and bacillus coli communis.	Streptococcus and bacillus coli communis.	After death (cultures taken 12 hours after death).	Fever commenced second day after miscarriage.	Death on sixth day after miscarriage.	*History.*—Miscarriage a few days before admission into hospital; admitted in "typhoid" condition and moribund; died before reaching ward. *Necropsy.*—Cultures taken from heart blood, spleen, lungs, and peritoneal sac all showed both streptococci and bacillus coli communis.
5	Full term, first pregnancy.	30	Streptococcus and bacillus coli communis.	Streptococcus and bacillus coli communis	After death (cultures taken 18 hours after death).	Fever commenced on seventh day after labour.	Death on twenty-first day after delivery.	*History.*—Placenta prævia and post-partum hæmorrhage; thrombosis of the left femoral vein with swelling of the leg noticed on the seventh day; high irregular fever and attacks of dyspnœa. *Necropsy.*—Cellulitis of the left broad ligament; thrombosis of the left common iliac vein. *Bacteriological examination.*—Cultures taken from the cavity of the uterus, from the vagina, and from the thrombus in the vein all showed both streptococci and bacillus coli communis.
6	Full term, third pregnancy.	—	Streptococcus and bacillus coli communis.	Not examined.	Ninth day.	Fever commenced on second day.	Death on eleventh day after delivery.	*History.*—Forceps used; lochia offensive and temperature 104° F. (ninth day). Antistreptococcic serum used just before death. No examination after death.
7	Full term, sixth pregnancy.	—	Streptococcus and bacillus coli communis.	Not examined.	Sixth day.	Fever commenced on second day.	Death on seventh day after delivery.	*History.*—Lochia offensive; temperature 104° F. (sixth day); treatment, intra-uterine douching and exploration; antistreptococcic serum used just before death.
8	Premature labour, fourth pregnancy.	33	Streptococcus, bacillus coli communis, and staphylococcus pyogenes albus.	Bacillus coli communis and staphylococcus pyogenes albus.	Tenth day.	Fever commenced on seventh day.	Death on fourteenth day after delivery.	*History.*—Premature labour a few days before admission into hospital; admitted after sudden attack of hemiplegia, high fever. *Necropsy* eight hours after death. Placental site necrotic; ulcerative endocarditis; cerebral embolism with meningeal effusion. *Bacteriological examination.*—Cultures taken from the heart blood, spleen, and meningeal fluid all showed streptococci in pure culture.
9	Full term, fifth pregnancy.	34	Streptococcus, bacillus coli communis, and staphylococcus pyogenes albus	Streptococcus, bacillus coli communis, and staphylococcus pyogenes albus.	Fifteenth day.	Fever commenced on fourth day.	Death on nineteenth day after delivery.	*History.*—Retained placenta, exploration and removal, lochia suddenly ceased; high intermittent fever and vomiting. *Necropsy* six hours after death. Uterus enlarged and softened; uterine mucosa necrotic; peritonitis; spleen, liver, and kidneys engorged and softened; heart muscle softened; disseminated lobular pneumonia; excess of fluid in peritoneal sac. *Bacteriological examination.*—Cultures taken from the heart blood, spleen, and peritoneal sac all showed streptococci in pure culture.
10	Full term (? eighth month).	37	Streptococcus, bacillus coli communis, and another bacillus (anaerobic).	Not examined.	Third day.	Fever commenced on second day.	Died on fifth day after delivery.	*History.*—Child, membranes, and placenta born before arrival of medical man; child dead, but movements noticed five days previously; temperature (second day) 104° F.; uterus explored and placental fragments removed; temperature (third day) 100°; vaginal discharge offensive; 102° (fourth day); antistreptococcic serum given on fourth day; laceration of the cervix and perineum. Patient had undergone an anterior nephrectomy 12 months previously; the operation wound had never quite closed and was still discharging pus.

a	b	c	d	e	f	g	h	i
11	Full term, first pregnancy	24	Micrococcus pneumoniæ, bacillus coli communis and staphylococcus pyogenes albus	Not examined	Tenth day	Fever commenced on third day	Death on fifteenth day after delivery	*History* —Contracted pelvis, delivery by forceps, temperature from 103° to 105° F (tenth day) vomiting lochia offensive *Necropsy* (incomplete) —Pelvic peritonitis and cellulitis of the right broad ligament, a portion of the placenta was retained, pleuritis, no pneumonia. (See 'A Case of Primary Infection of the Puerperal Uterus by Diplococcus Pneumoniæ," Foulerton and Bonney, Transactions of the Obstetrical Society, 1903)
12	Full term	—	Micrococcus pneumoniæ bacillus coli communis and staphylococcus pyogenes albus	Not examined	Eighth day	Fever commenced on sixth day	Death on ninth day after delivery	*History* —Patient was admitted into hospital on the seventh day she could only talk in Italian and little in the way of history could be elicited *Necropsy* —Placental site necrotic, cloudy swelling of the kidneys, no pneumonia *Bacteriological examination* —The same three species of bacteria isolated from the uterus during life were obtained on cultures taken from the uterus after death *Histological examination* —Sections made through the placental site showed necrosis of the superficial layer of tissue, inflammatory infiltration below this, and numerous well marked encapsuled diplococci
13	Full term third pregnancy	—	Diplococcus (+ Gram) pure culture	Diplococcus (1) and staphylococcus pyogenes albus	Eighth day	Fever commenced on seventh day	Death on fourteenth day after delivery	*History* —Post-partum hæmorrhage retained membranes, lochia natural, temperature 105° F (eighth day) No examination after death
14	Full term	—	Diplococcus (– Gram) pure culture	Not examined	Twelfth day	Fever commenced on seventh day	Died on fifteenth day after delivery	*History* —Forceps case, temperature 105° F (twelfth day) No examination after death.
B.—Cases of Severe Fever with Recovery								
15	Full term fifth pregnancy	—	Streptococcus (pure culture)	Streptococcus (pure culture)	Fifth day	Fever commenced on third day	Recovery on seventh day	*History* —Fifth day lochia normal, temperature 104° F, exploration of uterus, removal of placental fragments, and douching of uterus
16	Full term, eighth pregnancy	—	Streptococcus (pure culture)	Streptococcus and bacillus coli communis	Sixth day	Fever commenced on fourth day	Recovery on seventh day	*History* —Sixth day lochia offensive, temperature 104° F no special treatment.
17	Full term	—	Streptococcus (pure culture)	Streptococcus and bacillus coli communis	Sixth day	Fever commenced on third day	Recovery on seventh day	*History* —Sixth day temperature 103° F treatment Intra uterine douches
18	Full term	—	Streptococcus (pure culture)	Streptococcus and bacillus coli communis	Fifth day	Fever commenced on third day	Recovery on sixth day	*History* —Child born dead and macerated fifth day lochia natural, temperature 104° F, exploration of uterus removal of placental fragments and intra uterine douches
19	Full term fourth pregnancy	—	Streptococcus (pure culture)	Streptococcus, bacillus coli communis and staphylococcus pyogenes albus	Sixth day	Fever commenced on third day	Recovery on twenty fourth day	*History* —Sixth day lochia slightly offensive, temperature 104 5° F, exploration of uterus Intra uterine douches and antistreptococcic serum
20	Full term first pregnancy	—	Streptococcus (pure culture)	Streptococcus and staphylococcus pyogenes albus	Fifth day	Fever commenced on fourth day	Recovery on twenty fourth day	*History* —Forceps case fifth day lochia normal temperature 105° F exploration of uterus and intra-uterine douches
21	Full term first pregnancy	—	Streptococcus (pure culture)	Not examined	Eighth week	Fever commenced during first week	Recovery in fourteenth week	*History* —Eighth week purulent discharge from uterus, temperature 104° F, an anti streptococcic serum had been used abdominal section, chronic pelvic cellulitis
22	Full term first pregnancy	—	Streptococcus (pure culture)	Not examined	Tenth day	Fever commenced on third day	Recovery in fifth week	*History* —Tenth day lochia normal, temperature 105° F profuse sudaminal rash, no special treatment
23	Full term fourth pregnancy	—	Streptococcus and bacillus coli communis	Streptococcus and bacillus coli communis	Seventh day	Fever commenced on fifth day	Recovery on twenty first day	*History* —Forceps case, seventh day lochia offensive, temperature 104° F, exploration of uterus removal of placental fragments intra uterine douches, and antistreptococcic serum
24	Premature labour fifth pregnancy	—	Streptococcus, bacillus coli communis, and bacillus pyocyaneus	Bacillus coli communis	Twenty first day	Fever commenced fifth or sixth day	Recovery on twenty eighth day	*History* —Twenty first day signs of pelvic cellulitis, lochia purulent, temperature 105° F, intra-uterine douches
25	Full term sixth pregnancy	—	Streptococcus and staphylococcus pyogenes albus.	Streptococcus, bacillus coli communis, and staphylococcus pyogenes albus	Third day	Fever commenced on third day	Recovery on fourth day	*History* —Third day lochia slightly offensive, temperature 102 5° F, intra-uterine douches.

arthritic fluid it is necessary to use some culture medium to which fresh human blood serum has been added; but in the special circumstances of the present investigation such media were not usually necessary, as in most cases the uterine discharge itself consisted mainly of blood. In certain cases the discharge from the uterus was purulent and without any obvious trace of blood and in these cases micrococcus gonorrhœæ, if present, would not have been obtained in culture. In some of our cases, then, there has been this possible source of fallacy to which we will refer again when dealing with certain cases in which the contents of the uterus appeared to be sterile of bacteria; we need only add now that in none of the 54 cases of puerperal fever did the microscopic examination of freshly prepared smears made from the discharge show intracellular cocci such as might on further examination have proved to be micrococcus gonorrhœæ.

Examination of cervical secretion in non-pregnant women.—The cervical secretion in non-pregnant women was obtained in the majority of cases without the use of a speculum; the woman was placed in the semi-prone position and the vagina being rendered patent the secretion was taken by means of a "swab" of sterilised cotton-wool mounted on a long wire. In the case of some of the nulliparous women, however, a Sims's speculum had to be used in order to obtain free access to the os. In this series of cases, in addition to the set of culture tubes used for the uterine discharge in the previous cases, smears of fresh human blood on sloped agar were used in order to insure a suitable medium for the growth of micrococcus gonorrhœæ.

Results of the examination of the contents of the uterus in normal puerperia.—We commenced our investigation with the examination of the contents of the uterus in a short series of 12 cases in which the puerperium had up to the time of our examination been normal. In no case had the temperature up to the time of our examination risen above 99·6° F., and in none of the cases did any rise of temperature above that point occur subsequently. The result of our examination of these cases was that in every case the contents of the uterus proved sterile of bacteria. In all of the cases sufficient blood was smeared out over the surface of the media inoculated to insure the growth of micrococcus gonorrhœæ had that organism been present. The bacteriological examination of the uterus was carried out at periods varying from three to ten days after confinement and the patients included both primiparæ and multiparæ.

In seven out of the 12 cases a bacteriological examination of the lochia, as found in the vagina, was also made. In three out of these cases no growth of bacteria occurred; in one case we obtained a pure growth of bacillus coli communis; in one case a pure culture of staphylococcus pyogenes albus; in one case we found both these bacteria; and in the remaining case we obtained a pure culture of a diplococcus which did not stain by Gram's method, which grew freely on ordinary nutrient gelatin at a temperature of 20° C. without liquefying the medium, and which we subsequently found in the contents of the uterus in two cases of puerperal fever and once in the cervical secretion of a non-pregnant woman. Our results in this small series of 12 cases are therefore in accordance with the conclusions of those who believe that the uterine cavity in the normal puerperium is sterile of bacteria. And, incidentally, our results were useful as a test of the efficiency of our method for obtaining a sample of the contents of the uterus free from any contamination by the lochial discharge in the vagina—a question of some importance when the results of our examination of the contents of the uterus in puerperal fever come under consideration.

We do not propose to attempt to weigh the relative value of work which has shown the sterility of the uterine contents in normal puerperia as against that which has given opposite result. We would only point out that practically every likely source of fallacy in this investigation works in one direction; faulty clinical methods in collecting the contents of the uterus and errors due to imperfect bacteriological technique tend alike to the production of bacterial growth on the culture media when the uterus itself is sterile. And, in short, in a matter of this kind, negative evidence must carry rather more weight than positive evidence, which is founded on the appearance of growth on the media inoculated. Amongst those who have obtained growth from the contents of the uterus in normal puerperia are Döderlein and Winternitz who examined the uterus in 250 "afebrile" cases and found bacteria present in 43.

—	Day of puerperium on which the examination was made.											
	1st and 2nd.	3rd, 4th, and 5th.	6th.	7th.	8th.	9th.	10th.	11th.	12th.	14th.	15th.	Total.
Uterus sterile ...	2	3	27	10	30	52	39	34	8	1	1	207
Bacteria present	0	2	2	5	6	9	12	6	1	0	0	43

Vogel attempts to reconcile the contradictory results of different workers by the statement that the presence or absence of bacteria in the uterus has some relation to the stage of the puerperium at which the examination is made. He believes that in "afebrile" cases the uterine lochia are sterile during the earlier days but that in the later days bacteria will be found not infrequently. Vogel examined the contents of the uterus in two series of 15 cases each. In the first series of cases cultures from the contents of the uterus were attempted on the fourth day after labour, in the other series on the eighth or ninth day. The results were as follows.

—	Cases examined.	Sterile.	Streptococci found in—	Other bacteria found in—
Examined on fourth day	15	12	1	2
Examined on eighth or ninth day	15	5	2	8

The results obtained by Krönig must also be referred to. Krönig examined the uterine lochia of 63 "afebrile" puerperal women and found bacteria present in 13, streptococci in three, staphylococcus pyogenes aureus in one, micrococcus gonorrhœæ in four, bacillus coli communis in one, and anaerobic bacteria in six.

The contents of the uterus in cases of puerperal fever.—We may next proceed to consider the results of our examination of the contents of the uterus in cases of puerperal fever, together with some cases in which fever followed miscarriage. We have examined in all 54 such cases, as set forth in Table I., in which the cases are arranged in three series in accordance with their clinical severity. Series A includes two cases of miscarriage and 12 cases of labour at full term, all terminating in death. Series B includes four cases of miscarriage and 22 cases of labour at full term, in all of which the symptoms would be described clinically as "severe" and in which recovery followed. In every case the temperature rose to 102° F. or higher. Series C includes 14 cases of what would generally be termed "slight" fever after labour at full term. In none of the cases did the temperature exceed 102° F. and in all the rise of temperature, such as it was, constituted the main symptom of disease. In order to prevent any misapprehension we may explain how we arrived at this classification in series. After we had investigated our first 50 cases we arranged them in the three series under their respective numbers and, having regard only to the clinical symptoms recorded, our classification thus far was made absolutely without reference to the bacteriological findings; and it was only after we had thus grouped our cases into three series that we arranged individual cases in each series in accordance with the respective bacteriological findings. After our 50 cases had been thus classified and arranged we examined four additional cases, two of which terminated fatally and two of which recovered after symptoms of extreme severity.

Before proceeding to the detailed consideration of the bacteriological findings in these 54 cases we may mention that a few of our cases came from the wards of a lying-in hospital (all these cases are included amongst Series C). Some of the cases were attended in the obstetric out-patient department of a general hospital, amongst patients of the poorest class, and frequently living under the most insanitary conditions; others of the cases occurred in the private practice of various medical practitioners who were so kind *as to allow us to make the necessary examination.* Taken on the whole, then, our cases may be said to be fairly representative of general obstetric practice, but including, perhaps, an unusually high proportion of cases of severe illness.

The general results of the bacteriological examination in the 54 cases may be tabulated as follows:—

—	Sterile.	Bacteria found in—	Total.
Series A—Miscarriage	—	2	—
Labour at full term	—	12	14
Series B—Miscarriage...	—	4	—
Labour at full term	5	17	26
Series C—Labour at full term...	10	4	14
—	15	39	54

From Table I. it will be seen that out of 48 cases of fever after labour at full term 12 terminated fatally, giving a total case mortality of 25 per cent. Of 34 cases (Series A and B) in which after labour at full term the temperature rose to above 102° F. 12 died, giving a case mortality for this group of 35·3 per cent. In 48 cases of fever after labour at full term the contents of the uterus were sterile in 15 and contained bacteria in 33; the case mortality when bacteria were present in the uterus was 36·3 per cent.; in the other group of cases no deaths occurred. Of the 48 cases of fever after labour at full term the patient was a primipara in 21, a multipara in 23, and in four cases no information as to former pregnancies was obtained. The distribution of primiparæ and multiparæ in the three series of cases, excluding cases of miscarriage, was:—

—	Primiparæ.	Multiparæ.	Not known.	Total.
Series A—Severe cases, death	2	8	2	12
Series B—Severe cases, recovery ...	9	11	2	22
Series C—Slight cases, recovery ...	10	4	—	14
—	21	23	4	48

From this it will be seen that the relatively undue preponderance of primiparæ in our cases is mainly due to the relatively considerable proportion of them in Series C, a fact which probably is caused in part by the inclusion of a few cases from the wards of a lying-in hospital in which a large majority of the patients are primiparæ; and all of the cases quoted from this institution come under the description of "slight" cases. It will also be noticed that out of 44 cases in which the "parity" was known the primiparæ account for only two deaths as compared with the eight deaths amongst multiparæ.

(To be continued.)

A CASE OF MULTIPLE NEURO-FIBROMATOSIS.

BY H. LITTLEWOOD, F.R.C.S. ENG.,
SURGEON TO THE LEEDS GENERAL INFIRMARY; LECTURER ON OPERATIVE SURGERY IN THE UNIVERSITY OF LEEDS;
W. H. MAXWELL TELLING, M.D., B.S. LOND., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO THE HOSPITAL FOR WOMEN AND CHILDREN AT LEEDS; PHYSICIAN TO THE LEEDS PUBLIC DISPENSARY;
AND
S. G. SCOTT, M.A., B.M. OXON.,
SENIOR DEMONSTRATOR OF PATHOLOGY IN THE UNIVERSITY OF LEEDS.

CASES of generalised neuro-fibromatosis are sufficiently rare to be worth recording and the following case presents several features of interest.

The patient, a man, aged 47 years, was admitted to the Leeds General Infirmary for "multiple swellings of the body and limbs," pain in the left arm and leg, and great weakness. The history he gave was as follows. He had been a *perfectly healthy man until he was 30 years of age when the* first lump appeared in the right lumbar region. It had never been painful but had gradually increased in size until it was about as large as a duck's egg, when it was removed at another hospital some two months prior to admission. A similar but larger tumour was removed from the front of the right chest at the same time. He did not know what the nature of these tumours was made out to be. A number of other tumours had made their appearance in various parts of the trunk and limbs during the last 15 years; the only symptoms they had caused were some pains and slight dysæsthesia in the affected limbs; the pains in the arm and the leg complained of on admission were of this nature. About 11 months previously he had noticed a swelling in the hypogastric region which had increased in size up to the time of his present admission. He could give no definite idea of the size of it when first noticed. The only symptom which he had attributed to its presence was that he had had *to get up rather more frequently at night to pass urine,* but there had been no increased frequency in the day-time. He had lost two stones in weight during the last two months.

those which
on the back
uralgic pain
er causes at
the age of 79 years.

The patient looked as if he had lost flesh recently but was not strikingly emaciated or cachectic. In addition to the abdominal tumour there were found a number of smaller tumours scattered over the trunk and limbs. These varied in size from one-half of an inch to three or four inches in their long axis; they were fusiform or oval in shape; moveable to a varying extent; some were superficial and occurred along the course of the nerve trunks, others were deeper in the substance of the muscles and other tissues. They were firm, elastic, and painless to the touch. The skin was in no case adherent over them. A complete list of the situations in which they were discovered is given in the description of the post-mortem appearances.

The appearance of the abdomen was striking. There was a tumour in the situation and of about the size and shape of a pregnant uterus at the sixth month. On palpation it was smooth, firm, painless, and of uniform consistence throughout, so far as could be made out. It appeared to be fixed *somewhere in the pelvis but permitted some amount of lateral* movement.

As there were increased frequency of micturition and much constipation, which were thought to be due to the tumour filling up the pelvis, it was decided to attempt its removal and laparotomy was accordingly performed. It was then found to be adherent to the concavity of the sacrum by a short pedicle; there were also adhesions to the sigmoid flexure. It shelled out fairly easily but there was a good deal of hæmorrhage. *The patient died about four hours* after the operation from shock.

At the necropsy, 17 hours post mortem, the following conditions were found. There was a fair amount of blood extravasated into the peritoneal cavity. There was some erosion of bone about the middle of the concavity of the sacrum where the tumour had been adherent. It had also pressed on the left ureter, causing hydronephrosis with extreme secondary atrophy of the kidney. Tumours were also found in the following situations amongst others: (*a*) one of about the size of a hen's egg attached by strong adhesions to the lowest part of the right side of the sacrum; (*b*) one opposite the front of the eleventh left rib in connexion with a branch of the intercostal nerve; (*c*) in the substance of the left pectoral muscle; (*d*) on the left side of the lowest part of the rectum; (*e*) a small fusiform swelling in the course of the right median nerve; (*f*) opposite the left rhomboid muscle in connexion with a small branch of a posterior cutaneous nerve; (*g*) one of the size of a hen's egg in the substance of the left soleus; (*h*) a large tumour of about the size of a fist projected from below the edge of the left gluteal muscles (this proved to be part of a large multiple tumour-mass in connexion with the great sciatic nerve and extended up into the pelvis); (*j*) two small fusiform tumours in the course of the left pneumogastric in the neck; (*k*) a large *one, three inches long,* in the corresponding situation on the right side; (*l*) one of equal size and probably in connexion with the sympathetic, in the angle between the innominate and carotid arteries; (*m*) in connexion with the plexus gulæ, just at the passage of the œsophagus through the diaphragm (this was of about the size of a hazel-nut and was in direct continuity with a number of smaller tumours in this plexus, the solar plexus, and along the splenic artery); (*n*) a small one in the fissure beneath the liver; (*o*) in the spinal canal, in the cauda equina, and within the dura mater, one as large as a hazel-nut and two smaller ones (the nerves here presented the appearance of fusiform thickening in several places); and (*p*) one as large as a pea on the posterior root of one of the lowest dorsal nerves.

The large tumour had a very definite capsule and was of a uniformly oval shape with a slightly nodular surface. It measured approximately 20 by 15 centimetres in its diameters. On section it presented a loculated appearance in many parts, the loculi being due to areas of jelly-like degeneration which were either semi-opaque or translucent and of a bluish or greenish colour. There were many hæmorrhages into these jelly-like cysts, some of considerable size, and there were numerous small hæmorrhagic foci throughout the tumour. Most of the tumours presented an appearance identical with this one; generally the larger the tumour the larger the size of, and the more numerous were, the areas of degeneration. Only the smallest ones showed no degeneration. The brain was normal. Both lateral lobes of the prostate were enlarged and there were a few small gall-stones. There were no other abnormalities.

Histology.—The tumours received for examination were three in number. One was the large sacral tumour which had been removed by operation and which had been placed *en masse* in Kaiserling's solution (formalin, 400 cubic centimetres; potassii nitras, 15 grammes; potassii acetas, 30 grammes; and water, 2000 cubic centimetres) and transferred later to spirit. The second was a smaller tumour, about 3 by 1·5 centimetres, somewhat degenerated. The third was a small tumour, two by one centimetres, not yet degenerated, and with it was a considerable length of its nerve. The two latter were in the above-mentioned formalin solution when received, and were transferred to Müller's fluid in which they were kept some months. Pieces of all three were imbedded in paraffin by M. Heidenhain's (carbon bisulphide) method.

Pieces were cut from the large sacral tumour to include the growth, the hæmorrhage, and the jelly-like material. Externally, there was a thick connective-tissue capsule with many blood-vessels. No definite evidence of nerves could be seen in it. The tumour itself was a sarcoma, the growth consisting of elongated cells, some with several nuclei; the cells, as a rule, had several processes. Parts of the tumour, however, were more like a soft fibroma in structure, with small cells and an open network of fibres. A large part of the mass consisted of hæmorrhages and degenerate material of a homogeneous consistence. In some parts around these there was an open mesh-work in the tumour, infiltrated with plasma cells and red blood cells, and containing occasional mast cells. Masses of brown, highly refractile pigment were to be met with, particularly near the hæmorrhages. The tumour was fairly well supplied with blood capillaries, and round some of them, in sections stained with polychrom-methylene blue, there was a red colouration, probably metachromatic staining of mucin with the methylene-azur of the staining solution. The employment of Weigert's fuchsin-resorcin stain showed no elastic tissue in the tumour except round the vessels. The second tumour was uniformly sarcomatous, like the sarcomatous part of the large one, in the parts where it was not degenerated. There were no hæmorrhages in it but the degeneration exactly resembled that described above and around it were similar masses of pigment which appeared to be in some cases intracellular. The third tumour was uniformly sarcomatous, the growth exactly resembling the others. In two places, however, within this tumour strands of medullated nerve fibres were seen in sections stained by the Stroebe and Kultschitzky-Weigert-Pal methods. These nerve fibres appeared to be continuous with the tumour tissue, not demarcated from it by anything in the nature of a connective tissue sheath.

Relation of tumours to nerves.—All the tumours were definitely sheathed by a connective-tissue capsule. In the case of the smallest examined there were well-defined medullated nerve fibres stretched over the capsule. In the second tumour there were a few remains of nerve fibres in the same situation. Sections of the largest tumour were not stained to show this point as the material had been in spirit before it had been received for histological examination and thus was considered not suited for the necessary mordanting with chromium salts. But judging from the condition met with round the second tumour it is extremely improbable that any remains of nerve fibres could have been found. In sections stained by the Kultschitzky-Weigert-Pal method the myelin sheath was seen to be segmented, swollen, and varicose in some places and narrowed to fine fibrillæ in others. Staining by Stroebe's method showed variations in thickness, varicosities, and uneven staining of the axis cylinders. Sometimes one was to be seen ending abruptly in a corkscrew spiral as if it had been broken and retracted. In several places, principally near the tumours but also a few centimetres away from the third tumour, the connective tissue between the bundles of nerve fibres was infiltrated with polymorphonuclear leucocytes. Pieces of material from the third tumour, and the nerve a little distance away from it, showed no reaction of degeneration by Marchi's method. This means that either the myelin sheath had not undergone fatty change or that, if fatty change had taken place, it had occurred over seven weeks before death.[1]

This case is a good example of one variety of that group of cases to which the term "general neuro-fibromatosis" has been given. The several affections included in this group are as follows[2]: (1) multiple neuro-fibromata—generalised neuro-fibromatosis; (2) plexiform neuro-fibroma—plexiform neuro-fibromatosis; (3) molluscum fibrosum—cutaneous neuro-fibromatosis; (4) elephantiasis neuromatosa; (5) pigmentations of the skin associated with neuro-fibromatosis; and (6) "secondary malignant neuroma," being the sarcomatous transformation of one or other forms of neuro-fibromatosis. The best known variety of this group—multiple neuro-fibromatosis—can no longer be regarded, as formerly, as being due to the occurrence of multiple independent nerve tumours, in the strict sense of the word, but rather as local exaggerations of a diffuse or generalised overgrowth of the connective-tissue sheaths of the nerves. Each variety of the affection may occur independently and typically, but many cases occur which are intermediate, with every possible combination of lesions. The whole group is probably best known under the name of von Recklinghausen's disease, that observer having given in 1882 the first clear description of it, recognising the close relation of its various types. It is also known by the name, suggested by Bruns, "elephantiasis nervorum." The present case is an example of the last term of the series—secondary malignant neuroma.

As to the origin of the tumours the findings in this case harmonise completely with the generally accepted view that they arise from the endoneurium. The third tumour gives strong evidence on this point, which is strengthened by the description of a case by Sorgo.[3] Here some of the tumours were extremely small and in these he describes and figures multiple origins of the tumour concentrically round individual nerve fibres. Sorgo, however, goes on to say that the tumour originates from the neurilemma, a mode of origin *a priori* unexpected, and not, in our opinion, proved by his figure. Unfortunately, we did not see this paper until all the nerve-containing part of the third tumour had been cut up longitudinally, so we cannot compare transverse sections with his figure.

As to the effects of the neuro-fibromatosis on the nerve fibres we may further quote Alexis Thomson[4]: "The behaviour of the nerve fibres is one of the most disputed points in the morbid anatomy of neuro-fibromatosis and although the subject has received great attention, and although the most modern methods of staining the nerve fibres have been employed for its elucidation, it still remains undecided whether the nerve fibres participate in the morbid process or whether they remain passive and unaffected by the changes surrounding them. That the nerve fibres are lengthened as they pass over the tumour-like enlargements of the nerves or where they are dissociated from one another by the formation of new connective tissue between them, so that they pursue a wavy or spiral course, has been already referred to. Several observers have maintained that new nerve fibres are formed. ...... Although it is difficult to prove the negative, the new formation of nerve fibres may be regarded as unlikely in the absence of nerve cells. There is great difficulty in deciding the question as to the occurrence of degeneration in the already existing nerve fibres." And later: "It is very different in the case of sarcomatous transformation of the overgrown endoneurium, this being followed by the most extensive degeneration and destruction of the nerve fibres similar to that ...... occurring in the primary sarcoma of nerves."

[4] On Neuroma and Neuro-fibromatosis.

The findings in this case point to definite degeneration of nerve but whether this degeneration is due to the sarcomatous nature of the tumours or to their mere mechanical effects must remain to some extent uncertain. We hold the latter view, for, although the tumours were histologically sarcoma, they were still definitely encapsulated and capable of being shelled out. And there were no evidences of increasing disturbance of nerve function, such as is the rule in those cases in which sarcomatosis has supervened. The presence of leucocytic aggregations in the nerve is in harmony with degeneration in them and may be secondary thereto, as found by Ballance and Purves Stewart[5] in their work on nerve degeneration. So far as we know these leucocytic aggregations have not been described previously in this condition.

The distribution of the tumours in this case is, on the whole, typical. The involvement of one of the great plexuses (the lumbar), the occurrence of intramuscular tumours, and an extensive involvement of the sympathetic system are all common happenings. The vagus is far more frequently affected than any other cranial nerve. Implication of the nerves within the spinal canal occurs in about a quarter of all the cases and the nerves of the cauda equina are more usually involved. But the change is oftenest [illegible] which occurs [illegible] iem the same [illegible] nted out that [illegible] important particulars from primary sarcoma developing on previously normal nerves. About 17 per cent. of recorded cases of simple neuro-fibromatosis have developed sarcoma, and the sarcoma which occurs, while of the same structure as that which occurs in other situations, has the following peculiarities. Its onset, often in tumours that have existed for many years, is frequently determined by the removal of one of the tumours or other form of trauma, and while possessing a tendency to recur locally does not, with the rarest exceptions, give rise to metastasis but, on the other hand, is followed by a generalised sarcomatosis in the remaining tumours, and though the malignancy of these tumours is less than that of primary nerve sarcoma the cases invariably end fatally. For even if an early and successful removal of a tumour which has developed malignant features be carried out the patient is practically certain to sustain a fresh outbreak of sarcoma in other parts of his diseased nervous system. Our case illustrates some of the above points. One of the tumours (that which was removed) had taken on recent growth at a rapid rate and there existed throughout the other tumours a sarcomatous transformation, though not so extreme in degree.

Clinically, [illegible] increase in si[illegible] y ing structure [illegible] pain and loss of function of affected nerves, together with the usual accompaniments of wasting and cachexia. This case is probably in the stage of early and partial malignancy in the tumour removed (and but for which removal the patient might have lived some time longer), with early generalised malignancy in most, if not all, of the other tumours, which had not apparently given the usual clinical indications of such change. In this connexion the evidence of nerve degeneration described above is of special interest and importance, for the sarcomatosis of the tumours is so early that, in our opinion, they may be safely regarded as behaving in this respect like the simple tumours. The undoubted occurrence of such degeneration in simple neuro-fibromatosis has been noted in but a few cases, although of common occurrence where the tumour presents clinically the features of malignancy.

Two tumours had been removed two months prior to admission to the Leeds Infirmary and it is a matter for regret that the scars were not examined histologically. It is doubtful if this were the determining cause of the sarcomatosis which may have anteceded that event, although it may possibly have accelerated the progress of the disease.

The etiology of the affection is obscure. The only point of importance worth noting in this case is the influence of heredity, which has an especial bearing on the pathology. There have been only some 13 previously recorded cases in which heredity, or occurrence in families, has been evidenced and the particular variety of the affection was not always the same in the same family and the evidence occasionally not as convincing as in this case. Still, the proportion of cases in which such a factor has been traced, together with their frequent association with other developmental errors and their occurrence at birth or in early life, is such as to render very probable the view that it is a disease of the nervous system dating from intra-uterine life.

The clinical symptoms resulting from the presence of these tumours is, on the whole, remarkably slight, as is illustrated by our case, except in those which have undergone marked sarcomatous transformation, when they are the rule. But, as we have seen, the sarcomatous change in the present case, though generalised, was not sufficiently advanced to cause them. The absence of symptoms is often such that patients do not notice the presence of the tumours or cannot remember the date of their origin. An exception occurs, of course, where the tumours press upon the spinal cord or nerve roots or where there are effects from pressure on other viscera. (The ureter and kidney were involved in this case but it is not certain that any symptoms were referable to this.) This raises the interesting question as to how much pressure is necessary to cause nerve degeneration, in view of the rarity with which such degeneration has been found in these cases, and also how much degeneration is compatible with intact function, for here there were definite degeneration and very little evidence of disturbed function. Again, both vagi were freely involved, as is frequent, yet no symptoms referable to this fact seem to have occurred and this has been the rule in similar cases. The size of the abdominal tumour in this case is exceptional, though R. W. Smith, in his important memoir, records a still larger one.

We do not give a bibliography of the subject, for Alexis Thomson in his monograph, which we have freely utilised, has given an extensive one up to 1900 and we have noted no case of importance since that date.

THE TREATMENT OF TUBERCULOSIS OF THE LUNGS BY MEANS OF TUBERCULIN AND OTHER BACTERIAL DERIVATIVES.[1]

BY H. BATTY SHAW, M.D. LOND., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL AND TO THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON.

AT a time when the costly methods of sanatorium treatment are being so closely considered it is not at all out of place to view the other more directly combative measures which from time to time have emanated from the laboratories with the object of ascertaining whether they hold out any hope of a more economic means of dealing with so widespread a disease as tuberculosis or whether by their employment it may not be possible to supplement the results of sanatorium treatment and so increase the number of cases of cure and improvement. That there is room for improvement is shown by the figures quoted by Jessen.[2] Engelmann found that the German sanatoriums produced a leaving cure of 74 4 per cent.; after four years 79·9 per cent. of these patients were dead or unable to work. Even after four years only 44 per cent. of the cases in stage I. were able to work In Turban's cases after one to seven years 30·4 per cent of the first stage cases were able to work. In the Basler sanatorium at Davos after four years from leaving, counting all cases, 64·3 per cent. were capable of full work. Meissen[3] gives a report of what are described as the best results of an average stay of five months in the Hohenhonnef sanatorium—248 in number. From three to 11 years later 84 per cent. were sound and able to work, 16 per cent. had relapsed, and some of these, about 3·6 per cent. of the total, had died.

It is now some 14 years since Koch introduced what is known as the "old" tuberculin for the treatment of pulmonary tuberculosis. For many reasons the method fell into disrepute but now, probably because observers have learnt to be more patient and have carried out the treatment with less haste and more judgment and knowledge, there appears to be a tendency once more to consider the more direct attack of tuberculous disease by bacterial products combined with what is more usually understood as sanatorium treatment. Before proceeding to an account of these more direct methods it is necessary to call attention to several points. It will probably be not far wrong to say that in a general hospital cases of tuberculosis of the lungs are interesting from the single point of view of diagnosis and that when it has been decided that the disease is present the little that remains to be done in the case of the poor who frequent the hospital is to treat them symptomatically and to do all that is possible to prevent them from infecting those around them because in the large majority of cases the disease is too far advanced to allow of successful treatment by special methods. One of the first things to be discovered in a close study of tuberculosis of the lungs is that many phthisical patients live for years. Families may be decimated by tuberculosis, the source of infection being one of the parents who for years has been the subject of the disease but beyond having occasional attacks of bronchitis and "asthma" or winter coughs has had no symptoms calling for careful examination and treatment. The following is an account of such a family. The parents, both apparently well, have had 13 children. The first four and the seventh died at ages varying from a few weeks to four and nine months; it is impossible to say whether any of these were tuberculous. The fifth child died aged ten years from tuberculosis of the lungs; the sixth child, at six years, from tuberculosis meningitis; the eighth, ninth, and tenth children died at 15, 21, and 19 years respectively, all from tuberculosis of the lungs; there are three children living, one a girl, aged 28 years, quite well; another aged 18 years, who is well now but formerly was an out-patient at Brompton; and a boy, aged six years, who was brought to me and was found to be tuberculous. Both parents allowed themselves to be examined and the husband was found to be tuberculous. Such a history will serve to show how insidious a disease uberculosis of the lungs is and as quite possibly the father ad infected his children one after the other it will also now how necessary it is when once a case of tuberculosis of he lungs comes under observation to search for evidence of imilar disease in all those with whom the patient has been n contact.

Another point that requires consideration is the meaning f the term "cure." Loss of tissue cannot be made good ut it is quite certain that many people who have formerly ad the tubercle bacilli in their sputum are free from ymptoms of lung disease, have no tubercle bacilli in their putum, and are able to pursue their avocations in life with onsiderable success. Such a condition may be reasonably alled a cure, but by this we do not mean a cure in an absolute sense, such as we do of an attack of diphtheria. Tuberculosis of the lungs often is so slowly progressive that it does not fall to the lot of many physicians to be able to say they have watched such cases to the end and found that the patient has died at a good age from some other malady, the tuberculous diseases having entirely involuted. It is hardly necessary to recall the fact that the tubercle bacillus has only been certainly recognisable since 1882–84, when Koch discovered the organism and a certain method of recognising it. Advanced case of tuberculosis of the lungs where from three to five lobes are involved cannot be cured, though the disease may in favourable cases be arrested for a time. The problem, however, is very different when the question is raised whether a case with one lobe only involved, or a moderate amount of two lobes, can be cured. The answer is that such a case may be curable, but even in these cases it is not justifiable to say that a cure is certain, though it would be quite right to urge that such a case should be given every chance of sanatorium and other treatment.

Another point which should be carefully remembered is this, that it is not now considered so essential to spend time simply in investigating the degree of disease at any one part of the lung area, i.e., from what may be called a pathological point of view; to diagnose that the lung is in one or other of the three conditions of invasion, consolidation, or excavation is well enough in a post-mortem description, but from a practical point of view this method must be supplemented and what may be styled the "sanatorium" attitude must be adopted as well, and an endeavour must be made to discover rather how many lobes and what extent of each is involved at all. Turban[4] speaks of three stages: stage I., if only one lobe is the seat of moderate disease or if parts of two lobes are moderately involved; stage II., in which two whole lobes are moderately involved or one severely; and stage III., when the disease is more extensive than stage II. The adoption of this classification will save many rather unnecessary conflicts as to whether a cavity is or is not present and judging from the universal acceptation of Turban's grouping will serve to show how very necessary it is to know what are the superficial anatomical lines of separation of the various lobes and over what extent dulness to percussion, altered breath and voice sounds, and adventitious sound are present.

Lastly, it is necessary to remember the importance of detecting tubercle bacilli in the sputum, for cases of acute and chronic apical disease occur presenting even in the latter case the signs of cavities which are not due to tuberculous disease; unfortunately, tuberculous disease may be present without revealing any signs and the patient may not have any expectoration. If suspicious of tuberculous disease, judging from such ominous signs as wasting, night sweats, and hæmoptysis, it may be necessary to resort to the tuberculin test, though this requires the greatest care in application.

It must be very distressing for the public to hear that an observer whose experience is a very large one has recently been obliged to admit that the proportion of absolute cures of pulmonary tuberculosis, even when all methods are available, is not very large, if by absolute cure is meant the disappearance of symptoms and of abnormal physical signs, together with the loss of bacilli from the sputum. It would be most satisfactory if records of absolute cures were published in detail with special reference to the duration of the cure. Some observers even doubt that there is such a thing as an absolute cure of pulmonary tuberculosis when once the process has produced physical signs. This, however, is taking too sombre a view, for there are cases known to physicians of large experience in whom there has been an absolute cure such as has already been defined. Even if cases are not curable in an absolute sense patients may be told that so much can be done by open air and other treatment that life is greatly lengthened and you as medical men must be prepared with the knowledge of what cases are suitable for special treatment, for it is cruelty to send a hopeless case away from friends and home and it is a serious fault on the part of the medical man unnecessarily to put the friends to the cost of such special treatment. Naturally the authorities at sanatoriums aim at securing early cases for treatment, for such cases alone are capable of being cured, although not certainly.

1. *The tuberculins.*—The name "tuberculin" has been given to several potent agents which are prepared from the secretions of the tubercle bacilli or from the bodies of the bacilli. Robert Koch elaborated his first tuberculin in 1890–91 and this agent is sometimes spoken of as the "old" or original tuberculin (T). Designed at first as a remedial agent it has now become a most valuable diagnostic aid, but it is incorrect to say that it not used for remedial purposes because recently there have been published reports of its use, alone or combined with the newer forms of tuberculin, as an agent capable of materially improving the percentage cures of pulmonary tuberculosis. It is as well at this stage to remember that in this country the scepticism which followed on the failure of Koch's earlier attempts to cure cases of tuberculosis by means of tuberculin prevents not only the use of the old tuberculin for therapeutic purposes but even for diagnostic ones. In certain well-known continental sanatoriums the use of tuberculin in treatment is a common practice. Extended observations which have been carried out for many years with most rigid care and attention to detail on the value of the tuberculins are now being published and judging from the evidence which is brought forward it is impossible to avoid the view that tuberculins as a specific means of treatment have a real value.

The original or "old"-tuberculin is practically a glycerine extract of tubercle bacilli; it also contains some of the ingredients of the medium in which the bacilli are grown and some of the products of their own activity. The bacilli, which are not necessarily virulent, are grown in large shallow flasks containing slightly alkaline veal broth, glycerine, and peptone; free access is given to oxygen. After from six weeks to three months the bacilli will have [illegible] material. [illegible] 110° C. [illegible] a water [illegible] filtrate is again evaporated till it has reached one-tenth of its original bulk and is once more passed through a Chamberland filter. The resulting liquid is known as Koch's "original tuberculin"; it is brownish red in colour and the glycerine present renders it viscid. The old tuberculin has a specific gravity of 1179[6] and by means of this figure it is possible to convert the dosage from cubic centimetres to grammes. It is very common, however, to use measurement by centimetres when speaking of the old tuberculin. Unfortunately there is no exact standardisation of the old tuberculin; a rough one is that a full-grown guinea-pig should be able to tolerate 1 cubic centimetre and that a similar animal inoculated with tubercle bacilli should be killed by a dose of 0·1 cubic centimetre.

---

[4] Ueber beginnende Lungentuberkulose, Wiesbaden, 1899, S. 31.

The toxins present have been investigated by Hunter, Kühne, and others. Several alkaloids are present, possibly responsible for the febrile reaction following injection. In addition there are present three or four albumoses, one of which was formerly considered to be remedial and another responsible for the inflammatory reaction provoked around the foci of tuberculosis. Peptone has also been detected in the old tuberculin. Considerable doubt exists as to whether albumoses are the real toxic agents responsible for the changes following injection. It is more and more suspected that they act merely as carriers of the real active ferments which so far have not been isolated. The important point to remember is that old tuberculin is not only filtered but it is sterilised; risk of inoculation with this fluid is, therefore, practically impossible. The large proportion of glycerine present renders it possible to preserve the old tuberculin indefinitely so long as it is kept in a cool place. In 1897 Koch produced a series of tuberculins—Tuberculin Oberer, known as Tuberculin O, Tuberculin "rest" or Tuberculin R, and Tuberculin alkalinum or Tuberculin A. The reason for the introduction of these agents was that it was felt that the original tuberculin contained but little of the toxic substances capable of provoking in the human body anything approaching to immunity. A young growth of highly virulent tubercle bacilli is procured from glycerine serum; the growth is then dried in vacuo and thoroughly pulverised in a steel mortar containing non-glazed porcelain balls; this is preferably carried out by machinery and should last five or six days. The powder is then mixed with sterile distilled water and thoroughly centrifugalised for three quarters of an hour. The supernatant liquid is then removed and constitutes what is known as Tuberculin O. The residuum is again dried, further triturated, and emulsified with another supply of sterile distilled water and centrifugalised once more; the upper portion is pipetted off. The residuum left is treated by a repetition of the above processes until at last no residuum is left. All the fluids pipetted off at each stage, except the first, are combined and are known as Tuberculin R. To preserve the fluid a certain quantity of glycerine is eventually added but before this is done the tuber- [illegible] filter; unlike the [illegible] it. It will be seen [illegible] these newer tuberculins, first, because they are obtained from highly virulent cultures, and, secondly, because they are not sterilised. Tuberculin alkalinum—i.e., Tuberculin A—is obtained by extracting dried tubercle bacilli with decinormal soda solution and then filtering. It is no longer used as it invariably produces abscess formation at the seat of injection. Tuberculin O and Tuberculin A produce effects which are closely allied to those produced by the old tuberculin—i e., they intensify the necrotic processes [illegible] tuberculous foci. [illegible] is the agent which [illegible] local reaction at the seat of lesion or injection; it appears to produce immunity. Old tuberculin causes local reaction and necrosis around the lesion and apparently also possesses the power to some extent of producing immunity. The necrosis is probably due to the interaction of two agents—one present in the old tuberculin and the other in the infected individual.[6] Wright[7] includes old tuberculin and Tuberculin R in his classification of tubercle vaccines—i.e, those derivatives of the protoplasm of the tubercle bacillus which, on introduction into the body, are capable of producing substances which enter into chemical combination with the tubercle bacillus—the so-called "tuberculo-tropic" substances of Ehrlich. It must be noted that this use of the term vaccine is somewhat at variance with the more classical use of the term. The term vaccine is closely associated with the name of Jenner and his method of treatment consisted in introducing an attenuated but not necessarily sterile vaccine into the body to protect against small-pox.

The strength of Tuberculin R is such that one cubic centimetre contains 10 milligrammes of solid matter. The doses, however, are not expressed in cubic measure but by weight, not, it must be remembered, of the liquid but of the dried substance contained within it. This is an important matter, for unless accuracy is observed in dosage such potent agents as the tuberculins are capable of producing serious results, as was probably the case in one of three fatal cases occurring after the use of tuberculin.[8] This was due to a confusion of the dosage of Tuberculin R with the dosage of Koch's "new tuberculin," known now as the "emulsion of tubercle bacilli" or "bacillary emulsion."[9] This tuberculin is simply an emulsion of the powdered bodies of tubercle bacilli in a 50 per cent. solution of glycerine; the mixture is allowed to stand till all appreciable particles have sunk and the supernatant liquid is drawn off and is ready for use. There is no sterilisation and there is no filtration. Thellung[10] discovered a sample of bacillary emulsion which produced fatal results on injection into animals. The emulsion is interesting because, like Tuberculin R, it has a marked power of raising the agglutinating properties of the serum of the animal into which it is injected, by which is meant that the serum readily causes the clumping of tubercle bacilli. One cubic centimetre of the fluid contains five milligrammes of powdered bacilli.

Besides the above three groups of preparations derived from the tubercle bacillus by Koch, other agents derived in a somewhat similar way have been prepared by other workers. Some have been almost discarded and others are so new that little information at present can be obtained as to their value. One of these more recent tuberculins is know as Béraneck's. Its mode of preparation is briefly the following.[11] Tubercle bacilli are grown in a mixture of broth and solution of lime. This is then filtered and the filtrate which is evaporated to a syrupy consistence is claimed by Béraneck to contain a group of bodies which he calls basitoxins. The remnants of the tubercle bacilli which have not passed into the filtrate are then digested with a 1 per cent. solution of orthophosphoric acid and filtered. The filtrate contains a group of bodies described by Béraneck as acidotoxins. Experimentally, Béraneck finds that guinea-pigs are enabled by the injection of a mixture containing equal parts of the basi- and acido-toxins to survive inoculations with tubercle bacilli. Denys[12] has also prepared a tuberculin by growing tubercle bacilli in glycerine broth, then filtering and using the filtrate; no heat is applied. It will be thus seen that this preparation, though possibly containing materials that are destroyed by sterilisation (carried out by Koch, in the preparation of old "tuberculin"), is more dangerous by reason of the absence of sterilisation. Hirschfelder,[13] believing that toxins become antitoxins by a process of oxidation by the tissues, prepared tuberculin from a virulent strain of tubercle bacilli and then oxidised it *in vitro* by means of hydrogen peroxide; after sterilisation this preparation was injected for remedial purposes. Hunter[14] and Hahn endeavoured to separate the remedial albumoses from old tuberculin but, as has already been mentioned, there is reason to believe that albumoses are rather the carriers of toxins than the actual toxic agents. Ruppel[14] has separated from tuberculin what has been called tuberculinic acid, which, however, according to Behring and Kitashima[16] is closely allied to nucleinic acid.

Two other forms of tuberculin, or rather modifications, are known as Klebs's tuberculocidin and antiphthisin.[17] Klebs, also believing that the process of sterilisation adopted by Koch in the preparation of old tuberculin drove off certain important volatile constituents, dispensed with the use of heat and separated by special processes tuberculocidin and antiphthisin which are of the nature of albumoses but present enzyme action. Klebs was able to show that tuberculocidin was capable, after injection into an infected animal, of producing marked morphological changes in the tubercle bacilli. Finally, Hahn, following Buchner's methods, obtained by the hydraulic pressure of masses of tubercle bacilli a solution which he called tuberculo-plasmin. Von Ruck[18] has also prepared for use an aqueous extract of Koch's tuberculin, the attempt being made, as was Hunter's, to obtain an agent which produced no harmful symptoms.

2. Before dealing with the statistical part of the subject it will be well to turn to the other efforts that have been made directly to combat tuberculosis. Various workers have endeavoured to produce what are known as *antituberculous sera.* The principle of preparation is considerably different from that underlying the production of tuberculin, though the end in view may be of the same order—viz., to secure the neutralisation of toxins produced by the tubercle bacilli in infected individuals by the development of anti-bodies, to secure the production of bacteriolysins for the purposes of solution of the bacteria or to increase the function recently described by Wright (*vide supra*) as an opsonic pressure or power present in the serum, by which power the bacilli succumb the more readily to the digestive action exerted by the phagocytes of the blood.

Antituberculous sera are produced in the same way as antidiphtheritic serum. The first attempts in the direction of the use of antituberculous sera were made by Richet and Héricourt[19] who sought to render rabbits immune to experimental inoculation by the use of the serum of dogs—animals which are naturally immune to tuberculosis. Behring, Nissen, and other workers have shown that this method is useless. The next step was to inoculate animals with tubercle bacilli and Richet and Héricourt introduced virulent human tubercle bacilli into dogs; after six days the dog serum was obtained and introduced into the tuberculous patient and apparently with some good results. A further attempt was made by Behring and others to produce an antituberculous serum in animals by the injection of tuberculin. Babes and Proca attempted to check avian tuberculosis by the injection of dead or attenuated human bacilli. At this stage Maragliano developed his method, basing it on the idea that neither the old tuberculin nor Tuberculin R really contained all the toxins of tubercle bacilli. His tuberculin was really a mixture of two tuberculins to all intents and purposes like old tuberculin and Tuberculin R with the exception that for the preparation of the former virulent strains of tubercle bacilli were used; the one prepared by sterilisation contained, as old tuberculin does, a substance which causes a rise of temperature, and the other, like Tuberculin R, contained a substance which causes a fall of temperature. In 1899 Maragliano[20] described a variation of his earlier mode of preparation, using heat to 90°–95° C. instead of 100° C. To obtain an antituberculous serum he injected this toxic material into dogs, asses, and horses in increasing doses for several months and three to four weeks after reaching a maximal dose the animal was bled and the serum obtained. This serum is said to be both bacteriolytic and antitoxic.

Nicholls[21] has prepared a serum from goats by means of injections of Koch's Tuberculin R. The last of these antituberculous sera to attract attention is one introduced by Marmorek.[22] After discussing the effects of tuberculin Marmorek expresses the opinion that tuberculin introduced into tuberculous subjects stimulates the tubercle bacilli to produce a toxin which is capable of causing a reaction—rise of temperature, &c.—and he finds that this reaction is especially marked in cases of early infection. He has devised a special method by means of which he asserts that he is able to obtain this special substance. He uses a young culture of tubercle bacilli and cultivates in a special medium consisting of a mixture of glycerine broth and of a leucotoxic serum obtained from a calf which has been previously treated for a long time with injections of leucocytes obtained from guinea-pigs. In this medium the special toxic agent differing from tuberculin is produced; by means of the filtrate obtained from this medium Marmorek asserts that rabbits can be rendered immune against tubercle bacilli. In order to produce serum for curative purposes horses are injected with the filtrate during a period of eight months. The serum obtained from horses treated in this way renders rabbits immune against the tubercle bacilli, though at the time of writing Marmorek had not succeeded in making guinea-pigs immune against tubercle bacilli. The immunised rabbits on being killed were found to be free from tuberculous lesions, though control animals had succumbed to tuberculous infection following inoculation with tubercle bacilli.

3. *Vaccination against tuberculosis.*—The use of vaccines in tuberculous cases has already been referred to. It is, of course, quite clear that it is not meant that vaccination against tuberculosis is possible by means of the vaccine used against small-pox. It is in many ways unfortunate that the term should be used in any sense other than the original Jennerian one, because in the case of small-pox the actual ferment, organised or unorganised, has not yet been discovered, whereas in tuberculosis this difficulty has been surmounted. However, the term is in use and it is necessary to know what is meant by it. The idea is that tubercle bacilli may be so attenuated by various means that inoculation with them does not produce any tuberculous disease but is capable of producing anti-bodies. Such attenuated organisms have been introduced into lower animals or lower animals have been inoculated with avian or bovine tubercle bacilli. The serum of these inoculated animals has been used but then such treatment would, strictly speaking, be a serum treatment to which reference has already been made. No one so far has dared for prophylactic, diagnostic, or remedial purposes to inoculate a human being with a culture of tubercle bacilli however attenuated, and Maragliano's so-called vaccine described by him at the International Congress of Medicine at Madrid in 1903[23] is non-living so that it cannot be other than some form of tuberculin or serum. At this stage the question may be raised whether it is not a useless task to endeavour to produce immunity to this organism when almost all clinical experience and much experimental work tend to show that immunity against the tubercle bacillus is impossible of production. This objection no longer holds, since Wright[24] has not only demonstrated the possibility of increasing the defensive properties of the serum against this particular organism but has reduced the problem to positive mathematical proof.

Antistreptococcic sera.—The last method requiring attention is one which aims at overcoming the secondary infections which prove so serious when once tubercle bacilli gain access to the lungs. Some maintain that these other infections precede the tuberculous one. Before any of the above special methods of treatment are instituted it is necessary to reduce the fever by all the general methods, such as rest in bed, fresh air, &c. It is not possible in all cases to bring the temperature to the normal limit, for a pure tuberculous infection is capable of maintaining an elevation of a degree or so. Unfortunately general methods only too frequently fail to reduce the temperature to such moderate limits as 99° or 100°. To obviate this difficulty much attention has of late been given to the use of antisera calculated to overcome the other organism or organisms present in cases of mixed infection of the lungs, more especially the streptococcus. The difficulty in finding an antistreptococcic serum which will, in a remedial sense, fit the particular streptococcus causing different forms of streptococcic septicæmias is a very great one, so that it would be naturally expected that this method would be likely to meet with many failures. An effort has, however,

[24] Loc. cit.

been made to overcome this difficulty by the introduction of what is known as polyvalent antistreptococcic serum.

The application of tuberculin in treatment.—If the more special treatment with tuberculin is to be tried then certain rules advocated by Goetsch[25] and others should be followed. The patient should be free from fever or the febrile reaction should be very slight; the amount of tuberculin injected must not be increased unless the last dose has been tolerated without any reaction; the patient must be kept in bed on the day of injection as well as on the following day; if reaction takes place then the next dose should be of the same size as the one which preceded it; if a very marked reaction takes place then the dose is repeated at a longer interval, say, from four to eight days, and is reduced in amount; supposing no reaction occurs after each increasing dose then the intervals of injection should be two free days; these rules apply to the use of old tuberculin and bacillary emulsion. Petruschky[26] gives the following table of the doses of old tuberculin and bacillary emulsion to be administered at intervals as above directed and it will be noticed that both forms of tuberculin are measured by weight. As a vehicle Petruschky recommends a solution of pure carbolic acid one part, sodium chloride 1·5 parts, and distilled sterilised water 200 parts. The syringe kept specially for the purpose should be sterilised and the seat of injection should be cleansed with spirit and ether.

DOSES FOR ADULTS.

Old tuberculin (in milligrammes).—0·1 milligramme—0·25—0·5—1·0—2·0—3·0—4·0—6·0—8·0—10·0—15·0—25·0—35·0—45·0—60·0—80·0—100·0.

Bacillary emulsion containing five milligrammes of solid substance in one cubic centimetre (in thousandths of a milligramme).—0·1 thousandths of a milligramme—0·3—1·0—2·0—3·5—5·0—7·0—10·0—15·0—25·0—35·0—45·0—60·0—80·0—100·0.

Should the treatment with old tuberculin be badly tolerated it has been found beneficial to institute a course of bacillary emulsion as above indicated, continuing with it till a dose of 0·1 milligramme is reached, when treatment with old tuberculin in the doses above mentioned is recommenced. It is also found advisable to repeat the [illegible] even for several [illegible] by "intervals." [illegible] le and unfavourable signs during the treatment with tuberculin and in the near future it is probable that Wright's methods of estimating the opsonic power of the blood rather than methods for testing the agglutinative power will be used to supplement and possibly to replace the ordinary clinical estimates of the patient's improvement or the reverse and with an accuracy which is mathematical. The same means of estimating the changes in the opsonic power of the serum of a patient under treatment with tuberculin injections are also available for determining the time at which it is most favourable to carry out subsequent injections; an injection given during the negative phase of the phagocytic reaction as estimated according to the method of Major W. B. Leishman, R.A.M.C., may cause a greater depression of phagocytic power which, as Wright has shown, is due to a greater fall of opsonic power in the serum of the patient's blood.[27]

Results of tuberculin injection as shown by statistical records.—From a collection of 656 reported cases largely drawn from publications of Pottenger, *vide infra*, in which the tuberculins were used in the earliest stage of pulmonary tuberculosis, the percentage of cures in the sense already defined and in some cases observed for six years, in others for several months, averaged 91. In a series of 611 cases in a similar condition treated without tuberculins the average percentage of cases was 62—a difference of 29 per cent. In this last connexion, to show what a vast difference there is between the results obtained at sanatoriums where the circumstances of the patient are so much more favourable and the surroundings more conducive to improvement these figures may be compared with those of the Brompton Hospital. In 1902, 296 ordinary cases of tuberculosis of the lungs with one or two lobes affected were admitted; of these 22 per cent. only are reported much improved. In 1903, of 160 similar cases admitted 42 per cent. are reported as much improved. Trudeau has also given the results of two sets of cases of similar degree of lung affection; 46 cases treated with tuberculin gave a cure of a little over 80 per cent.; of 47 cases not treated with tuberculin 72 per cent. were cured in the same sense as the others. Turban[28] has given details of two sets of cases with tubercle bacilli in the sputum; of 86 cases treated with tuberculin 52·6 per cent. showed permanent good results and 47·7 per cent. were freed from tubercle bacilli in the sputum; of 241 cases not treated with tuberculin but with an equal degree of involvement of the lung and with tubercle bacilli in the sputum, 39·4 per cent. only showed permanent good results and only 27·4 per cent. were freed from the tubercle bacilli in the sputum. Turban[29] has also given the results of treatment in cases in which the disease had reached what he calls the third stage; 21 were treated with tuberculin and 75 per cent. were alive at the end of two years; of 84 similar cases not treated with tuberculin 50 per cent. only were alive at the end of two years. Lawrason Brown, reporting results obtained at the Adirondack Sanatorium,[30] found that in 325 early cases the percentage of cure of the total number was 63 per cent., as against 72 per cent. when tuberculin was used. This would indicate that tuberculin produced but very little improvement, and criticising the figures given by Brown it would really appear that 204 out of 282 cases were apparently cured without tuberculin, which is 72·3 per cent.—*greater* than the results with tuberculin. Pottenger,[31] collecting records of a large number of cases of tuberculosis of the lungs, irrespective of stage of severity, finds that 44·9 per cent. are apparently cured when culture products are used and only 13 per cent. when this method is not adopted. Moeller and Kayserling[32] speak most favourably of

the use of old tuberculin in 18 cases and also of the bacillary emulsion of Koch in seven cases. Klebs[33] gives as a result of treatment by tuberculocidin: Stage I., 16 cases, 16 healed; stage II., 22 cases, none dead, none unimproved; and stage III., 68 cases, 41 essentially improved. Jessen's results are as follows: Stage I., 14 cases, in all a great improvement; stage II., 11 cases, 55·4 per cent. decidedly better; and stage III., 11 cases, 36·0 per cent. improved; this is usual in this stage. Von Ruck,[34] using tuberculocidin and antiphthisin, finds an apparent recovery in 81 per cent. of cases in stage I., 35·1 *per cent. of cases in stage II., and 9 per cent. of cases in* stage III.

Use of Marmorek's antituberculous serum.—This serum is given either in two doses daily of two and a half cubic centimetres each or in one five cubic centimetres for four days followed by a week's rest. The administration for four days followed by a week's rest is repeated three times. An interval of 14 days elapses and then the above course is repeated. If the temperature of the patient rises at any time no more serum is injected for a week. Marmorek[35] finds no results in advanced cases of pulmonary tuberculosis or in cases of tuberculous meningitis but there is improvement in less advanced cases of disease of the lung; rapid absorption of fluid was found in two cases of pleural effusion. No untoward local or general reactions occur. Dieulafoy[36] reports the results of the use of Marmorek's serum on four cases of pulmonary tuberculosis, two with pulmonary and laryngeal tuberculosis and one with effusion. The serum did not appear to have a favourable effect on the fever, the sputum, or the general nutrition. The observations were carried out in September and October, 1902. Guinea-pigs inoculated with tuberculous sputum and treated with the serum died sooner than control animals simply inoculated with tuberculous sputum. Klein and Jacobson[37] collected 31 reports on the use of this serum as published by Rothschild-Brunier,[38] Montalti,[39] Jaquerod,[40] Latham,[41] and La Néele and de Cornières,[42] and contributed cases of their own. Their opinion is favourable to the use of the serum. Montalti reports on six cases: the least advanced were practically cured and four others were distinctly benefited. Jacquerod thinks the results quite justify a continuance of the method. Rothschild-Brunier made observations on one case the subject of tuberculous lung disease and on several others which were being treated for fistula and bone and joint disease. Latham's results of the use of the serum in pulmonary tuberculosis point to a definite specific action on the part of the serum but for remedial purposes he recommended that the serum should be applied in cases less severe than the ones in which he tried the method. Lucas-Championnière[43] was unable to observe any favourable results in a case of Pott's disease, in tuberculous abscess of the hip, tuberculosis of the lungs and testicle, and two other cases of local tuberculous disease. Béraneck[44] reports that his tuberculin has been tried in 90 cases, with and without fever, and thinks that he has seen improvement in 60 per cent. Paris[45] gives full details of the mode of administration and dosage of Béraneck's serum. After the injection a general rise of temperature may take place with malaise, headache, rigors, and profuse sweats. Paris has used it in 65 cases, 14 of which were in the first stage of pulmonary tuberculosis, 19 in the second, and 32 in the third. As a result of the treatment, all the first group were cured, seven of the second, and none of the third. Other than the effects mentioned above Paris found the tuberculin quite harmless and in some 5000 injections had no case of abscess formation. Maragliano's serum appears to be disappointing, but Mircoli[46] gives details of the results in 2899 cases with cure in circumscribed febrile and non-febrile cases amounting to about 22 per cent.

Finally, there remains to be considered the antistreptococcic treatment of pulmonary tuberculosis. Menzer[47] gives the results of 22 cases. 11 of these cases were the subjects of pulmonary tuberculosis in the first stage; eight were cured (disappearance of catarrhal signs and an average gain in weight of 12 pounds in three and a fifth months), and three, still under treatment, gained five pounds in a little over a month. Three other cases in the second stage showed improvement with a gain of weight. Five cases in the third stage also improved, gaining weight, and three others were unimproved. Bonney[48] reports his results in the treatment of mixed infection in pulmonary tuberculosis. Of his 26 cases, three were quite cured; distinct improvement was found in 17 *cases, though in eight of these symptoms alone were relieved,* the ordinary course of the disease remaining unchecked; in the remaining six cases no results were obtained. Ostrovsky[49] describes how Menzer's serum is obtained from horses which have been rendered immune against streptococci obtained directly from man. Ostrovsky reports the results of treatment of 24 cases, possibly including Menzer's cases. 12 cases were cured, ten were definitely improved, and two were relatively improved. The methods adopted to estimate improvement in these cases is unsatisfactory, so that cure has a very doubtful meaning.

I have thus endeavoured to bring before you the various materials which may be used for the specific treatment of tuberculosis and also the results obtained. No material has, so far, been before the medical world so long as Koch's tuberculins. Judging from the evidence it would seem that the use of the tuberculins materially improves the results of treatment. It would seem therefore quite justifiable to supplement the ordinary treatment by sanatorium methods with this specific one. Tuberculin treatment is of little use alone, so that its re-introduction, though of such material value, would not reduce the cost of treatment.

A CASE OF ŒSOPHAGEAL POUCH SUCCESSFULLY TREATED BY EXCISION.

BY A. BOYCE BARROW, F.R.C.S. ENG.,
CONSULTING SURGEON, ROYAL FREE HOSPITAL; SURGEON TO KING'S COLLEGE HOSPITAL;
AND
JOSEPH CUNNING, F.R.C.S. ENG.,
ASSISTANT SURGEON TO THE ROYAL FREE HOSPITAL.

THIS case is interesting both from the point of view of diagnosis and treatment as well as from the comparative rarity of the affection.

In February, 1904, a woman, aged 55 years, was admitted to the Royal Free Hospital with the diagnosis of epithelioma of the œsophagus. Her chief complaint was difficulty in swallowing which had been coming on for eight years. In 1897 she was treated for "bronchitis" by her medical attendant. In 1899 she attended a throat hospital and was recommended to have some carious teeth removed but no improvement followed. In 1900 she attended another hospital, again for "bronchitis," but without improvement. Her "bronchitis," she said, consisted in bringing up a large quantity of frothy sputum from the throat but she never suffered from cough. During the previous six months there was a marked increase in the difficulty of swallowing solid food. She volunteered the information that she had regurgitated, not vomited, food quite unchanged as long as three days after taking it. As instances, she gave a pickled onion and portions of rabbit. She also complained that stooping caused regurgitation and that she made a curious noise on swallowing. The patient looked so thin and half starved that several surgeons who saw her were tempted to say, "Oh! she looks as if she had malignant disease." On examination of the neck no swelling or enlargement of the glands could be detected, but on bilateral pressure over the œsophagus just below the level of the cricoid cartilage, a certain amount of gas could be squeezed up into the mouth. On swallowing two or three times gas could again be squeezed up. A medium sized bougie stopped eight inches from the teeth and could be felt to the left of the trachea. A small bougie could be passed into the stomach.

As an œsophageal pouch was now suspected from the history of regurgitation of unchanged food and from being able to squeeze up gas on pressure at the base of the neck two bougies were passed together. The first went into the pouch, the second into the stomach. The regurgitated food was examined for free hydrochloric acid but none was found. An attempt to throw some light upon the case with the Roentgen rays was unsuccessful. Metal bougies were used but seeing them at certain points in the neck was no evidence as to what prevented their onward passage. An attempt at filling the pouch with bismuth was also unsuccessful.

Operation by MR. BOYCE BARROW.—A large œsophageal bougie was passed eight inches from the teeth and could be felt in the neck below, and to the left of, the cricoid. An incision was made four and a half inches long from the left *sterno-clavicular articulation along the anterior* border of the sterno-mastoid muscle. The sterno-mastoid was pulled outwards, the sterno-hyoid and sterno-thyroid inwards, exposing the carotid sheath. The vessels were then retracted outwards and the trachea was displayed to the inner side. The red muscular wall of the œsophagus was then seen and lying to the left of it and behind it was a white fibrous-coated pouch one and a half inches long with the bougie in it. On tracing the pouch upwards its neck was discovered to be in the lowest part of the posterior wall of the pharynx. The bougie was now removed and the fibrous coat of the neck of the pouch was divided and turned back as a cuff. The mucous membrane was then ligatured and cut through and the fibrous coat was stitched up over it. A few stitches were put in to bring the muscular coat together over the site of the neck of the pouch. A drainage-tube was placed down to the wall of the œsophagus and the rest of the wound was stitched up. The drainage-tube was removed on the third day as no saliva had come through, showing that the stitches were holding and that there was no infection from the œsophagus. The patient was fed by nutrient enemata for seven days and was then able to swallow milk. At the end of a fortnight she was discharged with the wound healed and was able to swallow any kind of food.

Two months later the patient reported that she had increased seven pounds in weight, that she had no difficulty in swallowing, that there was no regurgitation, and that she was no longer troubled with the frothy saliva which had caused her to be treated for "bronchitis." Eight months after the operation she again showed herself and was then three and a half stones heavier than at the time of the operation.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

PURPURA AS A LATE COMPLICATION IN A CASE OF SCARLET FEVER.

BY JOHN W. MILLER, M.D. VICT., M.D. LIVERP., D.P.H. CANTAB.,

ASSISTANT MEDICAL OFFICER OF HEALTH OF BLACKBURN.

THE patient in this case was a boy, aged four years, who suffered from scarlet fever and was admitted into the Blackburn Fever Hospital under the care of Dr. Alfred Greenwood on Oct. 27th, 1904. The illness commenced on Oct. 25th and the attack was of a fairly severe type, the throat symptoms being well marked. Nasal discharge was present on admission to hospital. Otorrhœa commenced in the left ear on Nov. 1st and in the right ear on the 7th and these discharges continued until the child's death. His temperature ranged from a minimum of 98° F. at 6 A.M. on Nov. 8th to a maximum of 102° at 6 P.M. on Oct. 27th. The symptoms existing at the time of admission underwent gradual improvement until on Nov. 8th it was noted that the child's general condition was good and his temperature normal. His temperature remained normal until the evening of the 11th, when it was 102°. On the 12th there were enlargement of the glands of both sides of the neck and tenderness on pressure. The neck was more swollen on the 13th and 14th, which swelling diminished until the 17th, it then being slight and remaining so until death supervened. On the 19th at 10 A.M. hæmorrhage was first noticed in the tissues around the left eye, causing discolouration of the skin and swelling of the underlying tissues. There was also bleeding from both nostrils. On this day the temperature at 6 A.M. was 101° and at 6 P.M. it was 99·4°. On the morning of the 20th the skin around both ankles was seen to be affected by this hæmorrhagic condition over an area measuring one and a half inches by one inch. The skin was purplish-red in colour and there was some swelling of the underlying tissues. On the evening of the same day hæmorrhages, accompanied by similar discolouration of the skin, were noticed over the sacral regions (dimensions, four inches by four inches), the right hip (dimensions, one and a half inches by one inch), and both wrists (dimensions, two inches by one inch). The subcutaneous tissues over the right hip were markedly swollen and there was also swelling to a less extent over both wrists. The patient was now in a semi-comatose condition, very restless, and frequently crying out as if in pain. The respiration and pulse-rate were increased and the lips were blanched. The temperature on this date was 101° at 6 A.M. and 100·8° at 6 P.M.

On the morning of Nov. 21st it was found that the hæmorrhages had grown larger; the one in the sacral region now extended upwards towards the neck and outwards; the one over the right wrist extended upwards for about four inches and laterally across the whole breadth of the forearm; and the one over the left wrist extended laterally across the arm and upwards as far as the elbow. There was also more swelling of the underlying tissues. The condition of the patient during the day gradually became worse, the uræmia being more marked, and death took place at 6 P.M. from exhaustion. The temperature at 6 A.M. was 102·4° and at about 5.50 P.M. it was 100·6°. There were no other clinical signs beyond those mentioned. Astringent treatment internally failed to produce any beneficial effect. The urine was examined for blood and albumen on the 19th, 20th, and 21st, with negative result. There was no further bleeding from the nose after the 19th nor was there hæmorrhage from any other mucous membrane. The gums were normal. Inquiry failed to elicit any hereditary tendency to bleeding in the family. Two other brothers, who developed scarlet fever at the same time, have since recovered from the disease without any similar complication. The above-mentioned complication is exceptional, commencing during convalescence on the twenty-sixth day of the disease.

Blackburn.

NOTES ON A CASE OF TETANUS AND ITS TREATMENT.

BY FREDERICK W. HENDERSON, L.R.C.P. & S. IREL.

WHILE cutting hay on July 10th, 1902, a man was sharpening his scythe when he slipped and fell on it, cutting the palm of his hand. The cut extended from the head of the metacarpal *bone of the index finger in a circular form* to the base of the metacarpal bone of the little finger, deep down to the bones. The hæmorrhage was profuse, several arteries having to be ligatured. The wound was washed out with carbolic lotion and the edges were brought together with several sutures. Healing took place quickly without much discharge and the sutures were removed in a week or ten days' time. On July 25th symptoms of lockjaw set in which chloral and bromides controlled very well. On August 1st several spasms of the muscles prevented the patient from walking and in falling in his room he caught hold of a chair to draw himself up, in doing which the edges of a corner of the wound were partly pulled open. On the 5th tetanic convulsions set in very acutely, all the muscles of the back and the legs being violently convulsed every minute. A telegram was at once sent to Messrs. Parke, Davis, and Co. of London for antitetanic serum which was injected early that afternoon and again in four hours' time. This checked the convulsions and an injection was continued morning and evening till 15 bottles of the serum were used when the convulsions entirely disappeared. The wound was frequently washed with carbolic lotion and dressed antiseptically and was completely healed on Sept. 1st.

I think the case is worth recording as the convulsions were [illegible] serum was injected and the man [illegible] of September. Messrs. Parke, [illegible] be commended on their prompt despatch of the serum.

Elham, near Canterbury.

PATHOLOGICAL SOCIETY OF LONDON.

Subacute Atrophy of the Liver.—Prehistoric or Predynastic Vesical Calculus.—Imperforate Ileo-cæcal Valve.—Carcinoma of Adrenal.—Osteoplastic Carcinoma in Bones.—Obliterative Arteritis in the Prime of Life.

A MEETING of this society was held on April 4th, Mr. RICKMAN J. GODLEE, Vice-President, being in the chair.

Dr. S. G. SCOTT described a case of Subacute Atrophy of the Liver. An unmarried woman, aged 23 years, with a good previous history, had been jaundiced for eight months; there had been some vomiting and the fæces were clay-coloured. On admission to the Leeds General Infirmary nothing was made out on examination. Exploratory laparotomy shed little further light. Hæmorrhage supervened and caused death. The liver was small, soft, and wrinkled; it weighed 22 ounces (625 grammes). On section the cut surface was red with gamboge spots. These spots consisted of dead and dying liver substance. The red material was a very cellular connective tissue, in which were many glandular tubules. These tubules were arranged in rings round a central vessel. They were composed in their outer part of cells like those of the smallest bile-ducts, with which they were continuous. On the inner side towards the central vessel the cells were columnar, contained fat vacuoles, and secreted bile. Morphologically, however, they were not liver cells. Dr. Scott considered that these appearances were to be interpreted as regeneration of the liver lobule from the bile-ducts. He also suggested that there might have been recovery if hæmorrhage had not supervened but thought that coincidently with the regeneration a fibrosis would have taken place.—Dr. SCOTT, in reply to questions asked by Dr. F. J. POYNTON, Dr. F. PARKES WEBER, and Mr. GODLEE, said that the bile from the gall-bladder had been examined and was sterile and did not present any abnormality. There was no obstruction to the bile-duct though the gall-bladder was distended with bile. Doses of calcium chloride had been given to the patient before the operation but not to any large amount.

Mr. S. G. SHATTOCK exhibited a Prehistoric or Predynastic Vesical Calculus which was of much historical interest as proving the existence of urinary calculus at so remote a period. The calculus was found by Professor Elliot Smith in one of the graves of the prehistoric cemetery at El Amrah, in Upper Egypt, and was presented by him to the Museum of the Royal College of Surgeons of England. The presence of a vase of stone showed the grave to have antedated by many generations the time of Menes, the first dynastic king (B.C. 4800). The age of the calculus was thus at least 7000 years. It was found lying between the innominate bones of a boy, aged about 16 years, and it consisted of compact uric acid, which gave the usual chemical reactions, thickly encrusted with phosphates. Microscopic section of the uric acid body showed it to consist as usual of coarse pale-yellow crystals radially disposed in columns. After solution of the uric acid with caustic potash a transparent matrix was revealed as in normal circumstances. The complete absence of calcium oxalate was noteworthy. In India 70 per cent. of the urinary calculi consisted of this substance, which must be ascribed largely to the use of vegetable food-stuff. In the later dynasties the food of the ancient Egyptians was chiefly vegetable. It was interesting, therefore, to notice that the recent investigations on the prehistoric people showed that they were hunters; this appeared in the discovery of hunting lances of flint in the prehistoric graves in which clay models of kine had also been found. Immensely more interesting would the calculus have proved had it been possible to associate it with the bilharziosis commonly held to explain the great frequency of urinary calculus in modern Egypt, but this, in spite of an indefinite expenditure of time and care, the speaker had been unable to do. Had the chitinous capsules of the ova been present they would certainly have been preserved and would certainly have been discoverable. The occurrence of bilharziosis in the prehistoric age therefore was not as yet shown. Nevertheless, its possibility remained and it had occurred to him to question whether the bilharzial hæmaturia might be in some explanatory way related to the first of the Biblical Egyptian plagues, but a reference to the narrative would show the incongruities attaching to such an attempt. Mr. Shattock had had the opportunity of examining a second ancient Egyptian calculus from a tomb of the Second Dynasty; it contained no bilharzia ova though in its cortex was a cavity full of the coxidia of a mould. The coxidia looked so little changed that attempts were made to cultivate from them but no growth was raised. This calculus was found (with three others) in a grave excavated at Naga-ed-dêr by Dr. George A. Reisner on behalf of the Egyptological Expedition of the University of California, subsidised by Dr. Phoebe Hearst.—Dr. G. F. STILL referred to the passage of sand from the bowel and asked whether investigations had been carried out as to the nature of this sand. He had seen the condition occur in children who were the subjects of mucous disease.—Dr. POYNTON said that tophi when examined microscopically showed the same hyaline matrix which Mr. Shattock had described after dissolving out the uric acid crystals. The first step in the formation of tophi was the necrosis of tissue followed by a deposit of biurate of sodium in very fine crystals.—Mr. SHATTOCK said, in reply, that the intestinal sand which he had described was of vegetable origin. Dr. Garrod had described intestinal sand which was mineral in character.

Dr. J. CATTO exhibited a specimen of Congenital Occlusion *of the Bowel at the Ileo-cæcal Orifice.* The child was born in the practice of Mr. A. Hair and was admitted to the Great Northern Central Hospital with symptoms of complete intestinal obstruction, under the care of Mr. Peyton T. B. Beale. Despite an enterostomy the child died on the third day. At the post-mortem examination the child was found to be a well-developed male. The organs, other than the intestinal tract, were normal. The middle two-fourths of the small intestine were congested and were covered with recent fibrinous lymph, the coils adhering to each other and to the left anterior abdominal parietes. The contents for the same area were of watery consistence and of pea-soup colour, becoming greener and more inspissated as the cæcum was approached. The large intestine was of the size of a pencil and empty. It was bound to the posterior abdominal wall, having no mesentery developed. The obstruction was due to a complete septum at the ileo-cæcal orifice, probably produced early in embryonic life.—Dr. G. F. STILL asked whether the adhesions which had been described were old or recent. One of the explanations of these cases of obstruction was to attribute the condition to intra-uterine peritonitis. The obstruction was more frequently situated somewhat above the ileo-cæcal valve. He asked what the condition of the large intestine had been.—Dr. SCOTT referred to a baby with signs of intestinal obstruction who had a similar occlusion of the ileo-cæcal valve. The child died shortly after operation.—Dr. CATTO, in reply, said that the adhesions which were present in the abdomen were of quite recent origin.

Dr. W. BULLOCH read, on behalf of Dr. C. E. ADAMS, a communication on Precocious Development associated with Cancerous Tumour of the Left Adrenal Body. The case was identical in its clinical and pathological aspects with those communicated this winter to the society by Dr. Sequeira and Dr. Bulloch. The patient, a boy, was normal until the age of nine years when puberty set in which was associated with a remarkable development of hair on the face and great muscular development so that at the age of 14 years he had the appearance of a full-grown man. A large tumour in the abdomen was found to be inoperable and death ensued 17 months after the operation. The necropsy showed an immense tumour of the left adrenal body and extending into the liver which weighed 15 pounds. Microscopical examination by Dr. A. N. Ledingham showed the tumour to be a malignant hypernephroma.—Mr. GODLEE pointed out the long course which some of these cases of adrenal tumours ran.—Mr. SHATTOCK said that the external sexual characters were dependent upon something more than the presence of the testicles, for if the testes were removed from a cock it still retained its male characteristics. He suggested that the epithelium of the suprarenal glands probably had an important influence on these characteristics.

Dr. F. H. THIELE exhibited and described specimens showing Large Masses of Subperiosteal Growths around the ribs, the sternum, and the scapula following primary carcinoma of the prostate. The primary metastases occurred in the medulla of the bones and grew into the subperiosteal tissue through the foramina which exist in the bones for the passage of vessels. This had been shown by von Recklinghausen in his monograph. The specimens also showed marked osteoplastic changes in the bones; the ribs, the sternum, &c., were almost of the density of ivory. There was, however, no bone formation in the growths outside the bones. This was also described by von Recklinghausen who saw that this bony change occurred not only as an irritative change produced by the growth on the old bone but was an integral part of the carcinoma itself. It was not a peculiarity of any form of carcinoma but was simply a local attribute due to the transplantation of the growth into a soil which gave rise to bone. Bone formation occurred not [illegible] with other forms such as [illegible] the growth was the more [illegible] changes; the more sharply [illegible] the less osteoplastic changes occurred. The evidences of new bone formation were: 1. The presence of a small nodule of spongy bone in even the smallest extra-medullary growths. 2. The great sclerosis amounting almost to eburnation of some of the bones like the ribs, the sternum, and the femur. 3. The formation of bone in the [illegible] ases occurred most fre- [illegible] e thyroid, the prostate, [illegible] prostatic growths were [illegible]. The order of involvement of the bones was as follows: vertebræ, femora, pelvis, ribs, sternum, humerus, flat bones of the skull, fibula, tibia, radius, and ulna Bone metastases might produce erosion, expansion, infiltration and osteoplastic changes, and subperiosteal tumours and osteoplastic changes. The result depended upon the infiltrating or sharply defined nature of the metastases.—Dr. W. S. LAZARUS-BARLOW said that it was the growths which were mainly cellular which were more especially associated with metastatic growth in the bone, whilst those growths which were mainly fibrous invaded other tissues.

Dr. E. MICHELS and Dr. PARKES WEBER communicated a paper on Obliterative Arteritis leading to Gangrene of the Extremities in otherwise healthy men in the prime of life. The patient, a cigarette-maker, aged 39 years, a Jew from Roumania, had had his right leg amputated below the knee in 1889 after having suffered for over a year from severe pain in the foot and the muscles of the calf accompanied by a kind of "intermittent claudication" of the extremity. In June, 1903, he began to suffer in a similar way in the left lower extremity and in October, 1904, owing to a certain amount of gangrene together with intolerable pain and at the patient's repeated request, other treatment having been found useless, the left leg was amputated below the knee at the German Hospital. Since then the patient had been free from pain and the wound had healed well. Examination of the amputated extremity showed that the lumen of the popliteal artery was obliterated by connective tissue, apparently mainly resulting from organisation of a clot; the arteria dorsalis pedis showed extreme endarteritis obliterans. No changes were found in the veins or the nerves. Professor J. Israel had recently drawn attention to an idiopathic gangrene of the lower extremities occurring in men between 30 and 40 years of age, especially Russian Jews. Such cases had, according to him, been observed at Berlin, Königsberg, and Dorpat. Dr. Michels and Dr. Weber knew of three cases in London in poor East-end Jews, all of them between 30 and 40 years of age. There was no evidence that the affection was due to syphilis, alcoholism, renal disease, saturnism, ergotism, or premature senility. It was a question whether excessive cigarette smoking could play a part in the etiology—that is to say, in specially predisposed individuals.

LIVERPOOL MEDICAL INSTITUTION.

Br[illegible] cal Mastoid Operation.—A [illegible] ld on March 30th, Dr. J[illegible] the chair.

D[illegible]. JOHN HAY read a note on Bradycardia in which special reference was made to that form of pulsus rarus caused by "heart block." He described in detail the case of a man, aged 26 years, in whom the rhythm of the auricles was independent of, and different from, that of the ventricles. The following were the important features of the case. 1. Marked infrequency of the pulse, which varied from 17 to 30 beats per minute. 2. Transient loss of consciousness associated with disappearance of the pulse at the wrist. 3. Auricular contractions occurring much more frequently than, and independently of, ventricular contractions. 4. An enormous heart, weighing 29 ounces. The necropsy revealed no cause for this increased size. The heart was exhibited and also a drawing of it made by Dr. A. Keith of London, who was of opinion that there was a stretching of the auricular canal and also an attenuation of the bond between the base of the tricuspid valve and the base of the ventricle. The second case was that of a man, aged 62 years, in whom the heart block was not compl[illegible] conductivity, the time [illegible] the auricle to the ventri[illegible]. As a result of this only [illegible] was able to excite the [illegible] was 32 per minute and although the patient was apparently in good health he had a very much diminished area of cardiac response. The note was illustrated by charts, diagrams, pulse tracings, and lantern slides.—Dr. W. B. WARRINGTON, Dr. C. J. MACALISTER, Dr. R. J. M. BUCHANAN, and Dr. W. CARTER took part in the discussion.

Mr. ROBERT A. BICKERSTETH read a note on Prostatectomy and after quoting histories of cases in illustration of his remarks he discussed the circumstances which should guide the surgeon in his choice between the suprapubic and the perineal routes. He pointed out the necessity for a very full and careful ex[illegible] case and showed how it was [illegible] ay to distinguish in advance b[illegible] were easily removable and others in which removal might be a matter of very considerable difficulty. For the easier cases, which comprise the fibro-adenomatous enlargements and form the bulk of the cases requiring operation, the suprapubic operation, and enucleation after Mr. P. J. Freyer's method, was certainly the operation of choice. There remained other cases, however, in which it seemed likely that enucleation with the finger would be either very difficult or altogether impossible; for these the perineal operation was best, a transverse incision securing a full exposure and a good view of all the parts concerned. Lantern slides illustrating the successive stages of such a perineal operation were shown and the general indications for prostatectomy were further discussed.—Remarks were made by Mr. C. A. BALLANCE (London) and Mr. D. DOUGLAS-CRAWFORD.

Mr. HUGH E. JONES read a paper on the Difficulties and D[illegible] Mastoid Operation. After defining [illegible] to the work of Schwarze, Stacke, [illegible] numerated the difficulties peculiar to this operation: (1) the selection of suitable cases, which consisted in (*a*) limiting the complete operation to cases which really required it; (*b*) deciding whether to operate or not on cases where there was grave general disease; (2) avoidable difficulties on the part of the operator, such as working in a poor light or without an intimate knowledge of the anatomy of the part; and (3) unavoidable difficulties—e.g., variations in the position and size of the antrum, sclerosis of the bone, and a forward position of the lateral sinus. The facial nerve was the most important structure to avoid and there were several ways in which it might be injured: (1) by the faulty introduction or careless holding of Stacke's protector; (2) by the too free removal of the posterior wall of the meatus at its inner end; (3) the bone if brittle might be cracked by the chisel at a point not intended; (4) by careless curetting in the region of the fossa ovalis and sinus tympani; and (5) by curetting cells or fistulæ in the lower deep anterior part of the petro-mastoid or posterior wall of the meatus. The difficulties of skin grafting, provided the whole of the disease had been eradicated, were purely technical and could be overcome by practice and patience. Packing was advocated in cases in which it was not certain that the whole of the diseased tissue had been removed. The dangers peculiar to the operation were classified as follows: 1. Those arising from coincident general disease—e.g., advanced tuberculosis, diabetes, marasmus, and congenital syphilis in infants. 2. Coincident undetected intracranial disease—e.g., serous meningitis, latent [illegible] ical [illegible] and [illegible] result [illegible] foci [illegible] the [illegible] tor, [illegible] whether a general surgeon or an otologist, not only to be prepared to face and to learn to master any of the difficulties and dangers enumerated but also to see his patient safely through to a complete and final healing of the wound.—

Mr. Ballance also read a paper on the same subject.—Dr. W. Milligan said that the fundamental principles of surgery should be adopted in the treatment of septic disease of the temporal bone—viz., free exposure of the diseased area and the establishment of free drainage. The peculiar anatomical difficulties of this region should be studied very carefully before undertaking the radical operation. He exhibited various sections of the temporal bone in order to demonstrate some of the difficulties described by Mr. Jones. The treatment of the soft parts was of the utmost importance and he was an enthusiastic advocate of the grafting operation, which not only materially diminished the length of the after-treatment but secured more certain results, especially in so far as the healing of the inner tympanic wall was concerned. Continuous and light packing was irksome to the patient and to the surgeon and he was inclined to think that it tended to promote rather than to retard the growth of exuberant granulation tissue. In the treatment of tuberculous cases he advocated in the first instance merely providing efficient retro-auricular drainage, together with the removal of sequestra and later, when the general condition of the patient had improved, the performance of the radical operation.—Mr. W. Thelwall Thomas, Mr. E. M. Stockdale, Dr. Edgar Stevenson, Mr. J. Bark, and Dr. Warrington also took part in the discussion.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Pathology.

Exhibition of Specimens.

A meeting of this section was held on March 17th, Dr. H. C. Earl, the President of the section, being in the chair.

Sir W. Thornley Stoker, President of the Academy, exhibited specimens of a Columnar Cell Carcinoma of the Uterus in a very early stage and a Columnar Cell Carcinoma of the Rectum and Sigmoid Flexure also involving the left ovary.

The President of the section made a communication on cases of Human Actinomycosis and showed specimens from a case of Actinomycosis of the Right Kidney with a metastatic abscess in the cerebrum. He mentioned that many of the peculiar yellow grains were made up of dead organisms and cultivations were therefore not easy to obtain. He considered that the increase in the number of cases reported was due to better observation.—Mr. K. E. L. G. Gunn related particulars of cases which he had seen and also mentioned a case where, owing to the discovery of mycelial threads in the discharge, a mistaken diagnosis of actinomycosis of the rectum was given. Later the disease proved to be carcinoma.—Dr. T. P. C. Kirkpatrick mentioned a somewhat similar case occurring in the lip where a diagnosis of actinomycosis was at first made but subsequently this also was shown to be cancer.

Mr. Arthur H. Benson and Dr. H. C. Mooney showed sections of a Sarcoma of the Conjunctiva which formed a black tumour, of the size of a split pea, and had been removed from the conjunctiva of a married woman, aged 40 years. It was growing by a rather small pedicle from the conjunctiva of the globe, close to the sclero-corneal margin at the outer side of the left eye. The patient stated that she first noticed it 11 years ago as a very small dark reddish spot. For the past five years it had grown steadily but very slowly and some large vessels ran to its base. It was capable of being raised up with the ocular conjunctiva and was excised with scissors, leaving what appeared to be a perfectly healthy conjunctiva below it. The origin of the growth seemed to have been one of the small collections of pigment sometimes seen in a perfectly healthy conjunctiva. Its extremely slow growth, its low degree of malignancy, and its limitation entirely to the conjunctiva were remarkable.—Dr. Mooney, who had made sections of the tumour, said that it was composed of two parts, the larger one consisting of small spindle-celled pigmented sarcoma, the pigment being abundant, particularly near the periphery and round an excentrically placed non pigmented area. This non-pigmented area or core which was placed towards the base of the tumour, was made up of large swollen-looking epithelioid cells, loosely arranged with plentiful intercellular substance. Many of these cells had one or two vacuoles. The conjunctiva covering the tumour was for the most part thickened and at places cornified.

Mr. Gunn showed a specimen of Gangrenous Intussusception removed from a child; and sections, together with a model, of a Cancer of the Prostate implicating the wall of the bladder.

Leeds and West Riding Medico-Chirurgical Society.—A clinical meeting of this society was held on March 17th, Mr. E. Ward being in the chair.—Mr. H. Secker Walker showed two cases of Chronic Otorrhœa, the one being complicated with cerebral and the other with cerebellar abscess. Improvement followed on drainage of the abscesses. The patients were boys aged respectively ten and 14 years.—Mr. A. L. Whitehead showed a case of Retinitis Pigmentosa with Posterior Pyramidal Cataract, Degeneration of the Vitreous, and Optic Atrophy.—Mr. G. Constable Hayes showed a case of Optic Atrophy in a patient suffering from early locomotor ataxy. There was a three months' history of gradual loss of vision but the patient otherwise felt quite well. There was no history of syphilis. The symptoms observed were optic atrophy (with some choroido-retinitis), Argyll Robertson pupil, and loss of patellar reflexes.—Mr. Ward showed a man, aged 42 years, suffering from Gonorrhœal Stricture of the Urethra of 20 years' duration. 12 months ago abscesses formed in the perineum, burst, and formed again, and urine was passed through the abscess cavity. On Jan. 11th the stricture was completely excised, the piece removed being one inch long. The whole was imbedded in thick suppuratory tissue which broke down under pressure. The ends were united in the upper wall and a tube was put into the bladder. On March 7th a 9–12 instrument was passed without pain and without encountering any stricture.—Mr. H. Littlewood showed two cases of Colectomy for Malignant Disease of the Splenic Flexure, a case of Colotomy, a case of Splenectomy for Large Moveable Spleen producing several attacks of intestinal obstruction, a case of Splenectomy for Traumatic Dislocation of the Spleen with Twisted Pedicle, and a case of Pyloroplasty.—Mr. R. Lawford Knaggs showed a case of Appendicitis with Abscess, Fæcal Fistula, Pyopneumothorax, and Gastric Fistula. The patient, who was 13 years of age, began to suffer from acute abdominal symptoms on June 5th, 1904. On June 15th the contents of a pelvic abscess measuring three pints were evacuated through a median incision. On July 27th a fresh abscess reaching into the pelvis was opened and the appendix with concretions was removed. On August 8th the patient expectorated ten ounces of very foul sputum, following some lung symptoms. An empyema was localised at the left base. This suddenly became tympanitic and was incised on August 11th. On the 18th food began to come through the empyema opening almost directly it was taken. On Oct. 1st the patient was quite well, except for slight fæcal fistula which had since closed. Mr. Knaggs also showed a case of Punctured Fracture of the Orbital Plate of the Left Frontal Bone followed by Cerebral Abscess. The patient was admitted to hospital on June 11th, 1904, with a bone crochet hook transfixing the upper lip and orbit for three inches. The hook was removed. The orbital periosteum was separated and the aperture in the orbital plate of the frontal bone was exposed. The frontal bone was trephined, the left frontal lobe in the dura mater was raised, and the aperture in the dura mater was exposed. A small spicule of bone was removed from inside the aperture. Satisfactory progress was made till July when double optic neuritis, vomiting, and coma developed. On July 11th a second operation was performed. The frontal lobe bulged prominently on opening the dura mater. The results of exploration were negative and the flap was replaced. On the 15th a quantity of pus having a faint odour escaped by the drainage apertures. The protrusion of the brain, which had been increasing, began to diminish. Steady improvement followed and the patient was quite well on August 7th.—Mr. Walter Thompson showed a case of Rupture of the Small Intestine. The patient was a man, aged 20 years, who received a wound of the abdomen one and a half inches above the pubes, the left rectus being ruptured but the peritoneum not opened. There was blood in the cavity. Two ruptures were found in the small intestine about six feet apart. There was extensive laceration of the mesentery. 6 feet 6 inches of the small intestine were resected and union was accomplished by end-to-end anastomosis. A small peritoneal rupture in the sigmoid region was closed by suture.—Mr. H. Collinson showed a case of Compound Comminuted Fracture of the Humerus with Rupture of the Musculo-spiral Nerve.—Dr. T. Churton showed cases of Monocular Diplopia, Primary Optic Atrophy, and Osteo arthritis or Charcot's Joints. He also showed (with Dr. S. G. Scott) a case of (?) Acute Lymphatic Leukæmia.—Dr. A. G. Barrs showed a case of Spleno-medullary Leucocythæmia much benefited by the x ray treatment. The patient was a man, aged 43 years, of indoor employment. During the last four years he had experienced want of energy, early fatigue, and a gradual loss of one and a half stones in weight. During the last 12 months he had felt a [illegible] body. Treatment with [illegible] exposure being given [illegible] the abdomen and the knees. This was continued for 21 days. Thereafter the back was substituted for the abdomen. Some x ray irritation and folliculitis leaving pigmentation appeared on the abdomen three days after the abdominal applications were discontinued. After 20 days the white cells were only a quarter of the number they were at first. The polymorphonuclear neutrophiles increased from 61·6 to 83·2 per cent. The myelocytes decreased from 31·8 to 7·6 per cent. The spleen became first softer and then smaller; it was now about half its former size.—Dr. C. M. Chadwick showed a case of Multiple Tumours of the Abdomen and one of Cerebellar Tumour.—Dr. T. Wardrop Griffith showed cases of Early Disseminated Sclerosis, Hemiplegia (Anomalous), Primary Lateral Sclerosis, Disseminated Sclerosis, and Multiple Sarcomata.—Dr. E. F. Trevelyan showed two cases of Supposed Spinal Syphilis in men, also cases of Early General Paralysis, Localised Paralysis of the Extensor Communis Digitorum, and a case of Paralysis Agitans in a man, aged 50 years, coming on shortly after a severe injury to the head.—Dr. Carlton Oldfield showed a case of Birth Palsy. The child was helpless in mind and body. Although three and a half years old she behaved like an infant of five or six months. She had no speech but could hear well. The limbs could be moved freely but they were of no use because of their spasticity. Sensation was unaffected. Trophic disturbances were absent. The bladder and the rectum were quite under control. There was no tremor or athetosis.—Dr. W. H. Maxwell Telling showed a case of External Gastric Fistula. The patient was a woman, aged 34 years, who had suffered from dyspepsia since the age of 16 years. Symptoms of gastric ulcer (pain, vomiting, hæmatemesis), appeared between the ages of 22 and 25 years. At 25 years of age (July, 1896) she was admitted to Leeds Infirmary for these symptoms and loss of weight, together with "epigastric swelling" in the situation of the present fistula. This was a small, hard, tender mass, with the skin not adherent; it had appeared two weeks before. She improved considerably, gaining two stones in weight. On March 4th, 1905, she noticed that her clothes were wet and that liquids swallowed appeared through the fistula. Comment was made on the unusual nature of this case in that there had been no intermediate stage of abscess.—Mr. B. G. A. Moynihan, in discussing the case, drew attention to the fact that these fistulæ only tended to heal spontaneously when there was a sinuous tract of tissue intervening between the ulcer and the external opening.

Bradford Medico-Chirurgical Society.—A meeting of this society was held on Feb. 21st, Dr. C. F. M. Althorp, the President, being in the chair.—Dr. T. W. Hime read a paper on Compulsory Notification of Infectious Diseases in Bradford during 24 years considered as a preventive measure, with comparative reference to other towns. Dr. Hime pointed out that it was thought at the time of its introduction that compulsory notification would be the means of completely blotting out infectious diseases. As a matter of fact, however, since that time scarlet fever, enteric fever, and diphtheria had steadily increased year by year. He could not point to any remedy but he thought it was high time that steps should be taken to deal with these diseases.—Dr. J. T. Neech, medical officer of health of Halifax, said that there was a wide field for thought and reflection. He believed that many cases of so-called diphtheria were not diphtheria at all. Recently a special diplococcus had been found in the throat in these cases which required investigation.—Dr. S. G. Moore, medical officer of health of Huddersfield, doubted whether the increase was due to the fact that more cases were notified now than was formerly the case. Many cases of so called measles which were really scarlet fever were not notified at all.—Mr. H. Shackleton, Dr. R. H. Crowley, Dr. J. T. Kitchin, Dr. W. Scatterty, and Dr. F. W. Eurich also spoke.—Dr. Hime replied.——A meeting was held on March 18th at the Royal Infirmary, the President being in the chair.—The following pathological specimens were exhibited:—The President: (1) A Gall-bladder with 2505 Gall-stones removed from it; and (2) a Gall-bladder and Gall-stones removed from the Cystic, the Hepatic, and the Common Ducts.—Dr. H. J. Campbell: Stereoscopic Views of Specimens of medico-legal interest.—Dr. Crowley: (1) Colon with Perforation from a case of Ulcerative Colitis; (2) Perforation of a Tuberculous Ulcer of a Portion of the Intestine in the Sac of an Inguinal Hernia; (3) New Growth of the Trachea; (4) Carcinoma of the Lung; (5) Carcinoma of the Stomach; (6) Carcinoma of the Pancreas with Secondary Growths in the Liver; (7) Heart with Ulcerative Endocarditis; (8) Extensive Softening of the Brain, due to syphilitic arteritis; (9) Gumma of the Spleen; and (10) Liver and Spleen from a case of Banti's Disease.—Dr. Eurich: Microscopical Demonstration: (1) Neuroglia Scavenger Cells; (2) Calcification of Nerve Cells; (3) Elastic Fibre Stain (inflamed skin); (4) Degenerating Nerve Cells (spinal cord); (5) Persistent Thymus; (6) Ova of Bilharzia; (7) Actinomyces; (8) Fat stained with Sudan; (9) Senile Choroid Plexus; (10) Unusual Tuberculous Sputum; (11) Anthrax Spores; and (12) Anthrax Bacillus in tissues, &c. Various Cultures, &c., of Bacteria—especially the differentiation between the typhoid bacillus and allied species. Pathological Specimens: (1) Tuberculous Ulcers of the Intestine and Tabes Mesenterica; (2) Tuberculous Tumours in the Human Liver; (3) Tuberculosis of the Liver, the Spleen, and the Kidneys of the Pig; (4) Ovarian Cystoma; (5) Extensive Subarachnoid Hæmorrhage (Anthrax); (6) Laryngeal Diphtheria with Interstitial Emphysema; (7) Pericarditis; (8) Partial Placenta Prævia (fourth month); and (9) Hæmorrhage into the Spinal Cord and other preparations.—Mr. J. Basil Hall: (1) Specimens of Myoma Uteri removed by Abdominal Hysterectomy; (2) Specimens of Carcinoma Uteri removed by Abdominal Hysterectomy; (3) Epithelioma of the Colon from a case in which the Transverse Colon and part of the Bladder were excised; (4) Ovarian Cyst becoming Gangrenous from Torsion of the Pedicle; (5) Growth of the Cheek implanted during the removal of an Epithelioma of the Palate and Tonsil; (6) Tumour of the Testis; (7) Sarcoma of the Axilla; and (8) Growth of the Penis.—Mr. W. H. Horrocks: (1) Sarcoma of the Testis; (2) Ectopic Gestation; and (3) Fibroma Uteri.—Dr. Rabagliati: (1) Four cases of Abdominal Hysterectomy; and (2) Two specimens of Myoma from Hysterectomy.—Dr. T. J. Wood: (1) Hydatiform Degeneration of the Chorion; (2) Hypertrophied Prostate removed by Operation; (3) Liver showing Calcified Hydatid Cyst which caused no symptoms till accidentally ruptured; (4) Bladder and Kidneys showing Tuberculous Disease; (5) Epithelioma of the Lower Jaw from a woman, aged 36 years; (6) Ovarian Cystoma with Papillary Growths; (7) Suppurating Ovarian Cyst with great Enlargement of the Fallopian Tube; (8) Vesical Calculi; (9) Renal Calculi; and (10) Biliary Calculi from the Common Bile Duct and Cystic Duct.

Clinical Society of Manchester.—A meeting of this society was held on March 21st at the Palatine Hotel. Dr. E. S. Reynolds being in the chair.—Dr. H. Ashby opened a discussion on Vomiting in Infants and after briefly describing the structure, movements, and innervation of the stomach pointed out that vomiting, being a reflex act, might be physiological or pathological, or might partake of the character of both. As a physiological reflex it might be useful in overloaded stomachs; as a pathological reflex it might indicate cerebral or other disease. It might take place by the contraction of the stomach alone or by the abdominal muscles, or by the union of both. Chronic vomiting or regurgitation shortly after food was of no significance unless it was accompanied by loss of weight and might be looked on as a safety-valve action. In such cases less food should be given. If accompanied by loss of weight and it succeeded an acute gastritis it was often most obstinate, as there were extreme irritability of the stomach and impaired power of digestion. A residue of food, mostly curd, always remained in the stomach after the digestive process had ended. This decomposed and fermented and when another meal was given this condition became worse and a habit from the first hour after it is known to be contracted, when it readily yields to simple management; also that it is often a dangerous thing to leave a cold to take care of itself. "The Golden Rules Index" is contained on five pages and is a summary of the entire book "as an aid to the memory." The five chapters into which the book is divided deal successively with the nature and treatment of colds; with hints on cleanliness and bathing; with hints on clothing; with pure air and ventilation; and with alcohol and its relation to health and cold. The text is sound and sensible and the treatment recommended is judicious.

The Sewage Problem: A Review of the Evidence Collected by the Royal Commission on Sewage Disposal. By ARTHUR J. MARTIN, Assoc.M.Inst.C.E., M.R.San.I. London: The Sanitary Publishing Co., Limited. 1905. Pp. 363. Price 8*s.* 6*d.*—The evidence so far taken before the Royal Commission on Sewage Disposal amounts to a very valuable collection of practical information upon the subject. The Commission was appointed early in the year 1898 and its labours are not yet concluded. It has, however, issued several reports which are calculated to give considerable assistance to those local authorities who have to face the question of sewage disposal. Everyone knows what a difficult task it is to extract complete information upon any given point from a mass of evidence. Mr. Arthur J. Martin has immensely simplified this task for those who seek information on the sewage problem by publishing in the volume before us a digest of the more important evidence on some of the practical points which are dealt with. He has written a continuous story in which certain paragraphs of evidence are inserted so that, as he says, the witnesses so far as possible speak for themselves. The result is a book in which the present position of the question is clearly reviewed. The author's task could not have been light and he has kept the several branches of the subject quite distinct and has succeeded in quoting just that evidence which is required. Further, he has dealt with the whole question, so far as it has been investigated by the Royal Commissioners, with an open mind. This labour of scientific compilation will be widely appreciated by all those concerned in this great sanitary question.

Practical Exercises in Chemical Physiology and Histology. Arranged by H. B. LACEY and C. A. PANNETT, B.Sc. Lond. Cambridge: W. Heffer and Sons. London: Simpkin, Marshall, and Co. 1904. Pp. 112. Price 2*s.*—This book consists of a compilation of practical exercises in chemical physiolology and histology, the authors having drawn upon several well-known standard works on the various branches of the subject. The work should, therefore, be convenient to the student commencing a course of practical physiology and histology. Whilst not presenting any novel feature in the plan adopted or offering any new observations the exercises bear the impression of having been tested practically by the authors. The exercises are admittedly arranged to meet the requirements of students preparing for the physiology examination, stages I., II., and III. and Honours, of the Science Department of the Board of Education. The examples given of quantitative analysis are few and somewhat prosaic.

Neolithic Dew Ponds and Cattle Ways. By ARTHUR JOHN HUBBARD, M.D. Durh., and GEORGE HUBBARD, F.S.A. London: Longmans, Green, and Co. 1905. Pp. 71. Price 3*s.* 6*d.* net.—The memorials of our primitive ancestors have an abiding interest for us who are alive at the present day and these little islands are very rich in such memorials. Scattered over nearly the whole of the south of England are many so-called "British camps" and of these two are specially notable—namely, Chanctonbury and Cissbury Rings on the South Downs. With these gigantic earthworks are closely connected that curious feature of a down country, the dew ponds, and in the book before us Dr. Hubbard and Mr. Hubbard have set themselves to elucidate the connexion between the earthwork, the dew pond, and the cattle track. The physics of a dew pond are first considered and it is pointed out that their perennial supply depends upon the complete insulation of the water-containing area from the surrounding earth. This is effected by means of a layer of dry straw which is then covered with finely puddled clay. Such a pond loses heat rapidly at night, thus bringing about condensation of the atmospheric moisture. In reference to this point an interesting letter appeared in our contemporary *Nature* of Sept. 20th, 1900, in which the writer, Mr. Arthur Marshall, put forward the theory that a difference of electrical tension was responsible for the deposition. During the night of April 1st, 1899, he exposed two porcelain basins on a ridge of the South Downs. These basins were supported by silk threads and in each of them was placed a sheet of copper. This sheet was in one case earthed by means of a wire, but in the other case it was insulated by the silk threads although the insulation was imperfect owing to the threads becoming wet. In the morning the basin with the earthed copper contained 18 cubic centimetres of water while the other contained only 15·5 cubic centimetres. It is not, however, the physics of the dew pond which concern Dr. Hubbard and Mr. Hubbard so much as the economic aspects of these structures and they have collected much evidence to show that dew ponds were closely connected with the water-supply both for the dwellers in the earthworks and their cattle. Besides Chanctonbury and Cissbury other earthworks, such as Maiden Castle, Ogbury and Figsbury Rings, are dealt with and also, though it has no connexion with dew ponds, Maumbury Ring. The book is of great interest and well worth reading.

Exercises in Practical Physiological Chemistry. By SIDNEY W. COLE, M.A. Cambridge: W. Heffer and Sons. London: Simpkin, Marshall, and Co. 1904. Pp. 152. Price 5*s.*—Text-books on practical analyses are often disappointing in practice inasmuch as it is sometimes found that the directions given in order to obtain a definite result do not succeed. This is invariably due to a want of attention to detail on the part of some writers of text-books when dealing with experimental procedure. There are many chemical tests, for example, which, if they are to succeed, must be conducted in a certain way and frequently it happens that the addition of reagents in a certain order must be observed. The kind of blemish described does not apply to Mr. Cole's exercises and this is not surprising since he has first worked through and obtained the results stated in each and every exercise given in the book. In view of the fact that 248 exercises are thus presented it follows that the author has mastered those details which are essential to a successful issue. The exercises cover more ground than is at present necessary for most examinations in medicine, so that the plan is to give the student a general knowledge and not a mere acquaintance with a part of it which suffices for examinational purposes. The directions in which failure or success may follow are clearly indicated. A somewhat novel plan adopted in the book is presented in the spaces provided at the end in which the student may draw various crystalline forms from preparations made by himself. At the foot of the blank sheets the name and description of the preparation are given. In a similar way a blank chart is provided for recording absorption spectra. Mr. Cole clearly understands how students should be taught practical methods and how their powers of observation should be trained and no more need be said in bringing his book to the notice of those about to commence a course of practical or physiological chemistry.

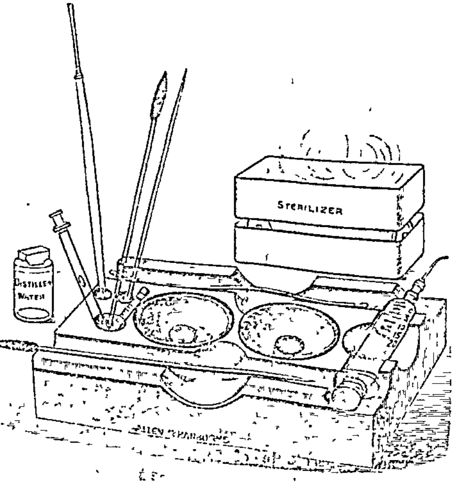
Simple Methods of Testing Sewage Effluents. By GEORGE THUDICHUM, F.I.C. London: The Sanitary Publishing

Co. 1904. Pp. 60. Price 2*s.* 6*d.*—This is a handy little guide to the testing of sewage effluents for works' managers, surveyors, and others. The methods are, on the whole, quite simple and are described in terms which should be easily intelligible to those engaged in the management of sewage works. While many analytical processes which are conducted with the view of obtaining an idea of the extent of purification effected by a given process can only be carried out by the trained chemist, there are many simple operations which the intelligent works' manager can perform for himself and which give valuable indications as to the efficiency of the purifying plant. In such a case this book supplies just the information needed and within the limitations indicated.

New Inventions.

A NEW DRESSING SLAB.

IN the illustration there is shown a glazed earthenware slab measuring four and three-quarter inches in length by three inches in width by three-quarters of an inch in thickness. It serves as a support for lacrymal or hypodermic syringes, glass rods tipped with wool, probes, and similar instruments. On it there are formed (1) two long shallow grooves and one shorter groove for receiving instruments, each groove being provided with a central bevel; (2) two crater-like depressions capable of holding one fluid drachm, each having at its lowest point a recess of a capacity of five minims whereby a syringe is enabled to draw up the last drop of the contained solution; and (3) one large and two small wells in which various articles can be placed upright, a syringe or a glass cylinder in the larger well and a glass rod or the nozzle of a syringe in the smaller ones. The lid of the box in which the slab is kept is washable and can be used as a cover for the slab when the latter is standing on the table and the sterilised instruments are *in situ* ready for the surgeon. The slab is easily rendered aseptic by boiling, it cannot be overturned, and will be useful in consulting rooms where small quantities of expensive drugs are employed. The price of the slab is 2*s.* It is supplied by Messrs. Allen and Hanburys, 48, Wigmore-street, London, W.



Harley-street, W. R. E. HANSON, M.A., M.B. Cantab.

ACCIDENTS (MINES AND FACTORIES) BILL.

WE have received the following letter from the honorary secretary of the Metropolitan Branch of the Association of Certifying Factory Surgeons concerning the above-mentioned Bill, which is down for second reading on April 10th.

OBJECTIONS OF CERTIFYING FACTORY SURGEONS' ASSOCIATION TO ACCIDENTS (MINES AND FACTORIES) BILL AT PRESENT DOWN FOR SECOND READING.

To the Editors of THE LANCET.

SIRS,—*Clause 4 proposes* to aboli [illegible] the cause of machinery accidents [illegible] certifying factory surgeon. As re [illegible] only report received by the Factor [illegible] employer.

Employers' Reports are Misleading.

We are able to say through our [illegible] employers do not form any tru [illegible] occurred; their reports are often [illegible] to suppose that an employer will [illegible] due to his machinery being improperly guarded.

Clause Unworkable.

Sub-clause 5 proposes that the Secretary of State shall direct that certain accidents be investigated by the certifying surgeon. We believe that this would be quite unworkable and would result in no accidents at all being investigated by him. No matter how carefully drawn up such directions were it would be impossible for the local [illegible] year.

[illegible] Secretary of State already possesses power under Section 20, Factory Act, 1901, to obtain this information from the certifying factory surgeon.

Evidence of Injured Person.

[illegible]

Objections raised by Home Office.

The objections which may be raised to this scheme are: (1) The trouble to the occupier of sending two notices; (2) that trivial accidents would be unnecessarily reported; (3) the cost of surgeons' fees; and (4) that surgeons' reports are of no use.

Objections of Home Office Answered.

1. No trouble has been experienced up to the present by the occupier having to send tw [illegible] certifying surgeon [illegible] course of a year.

2. We do not agree that [illegible] should not be investigated [illegible] these often reveals serious [illegible] remedied, thus preventing [illegible] future.

3 The total sum paid by Government to certifying surgeons for accident fees does not exceed £6000, a very small sum considering the amount of good which is obtained for it.

4. Times without number it is found on visiting factories that [illegible]

W. H. F. OXLEY,
Hon. Sec. Metropolitan Branch Association of
119, East India Dock road. Certifying Factory Surgeons.

PS.—We think there are some good points in the Bill, such as the [illegible] accidents. We think that the Bill should be [illegible] endment [illegible] Clauses a [illegible]

HOSPITAL SATURDAY FUND.—The annual general meeting of the Metropolitan Hospital Saturday Fund Association was held on April 1st at the offices, Gray's Inn, Mr. W. V. Stratford presiding. The report of the council for 1904, which was adopted, showed that the receipts from the workshops and business houses had reached £24,344, the highest recorded in the history of the Fund, being an increase as compared with last year of £670.

THE LANCET.

LONDON: SATURDAY, APRIL 8, 1905.

The Expenses of Public Vaccination.

THE report of the departmental committee of the Local Government Board on the expenses of public vaccination has at last been laid before Parliament. The committee sat in the autumn of 1903, concluding its labours in December of that year, and the report is dated April, 1904. It must be inferred from this delay that the Government intends to remodel the Act this session instead of re-enacting the measure as it now stands on the Statute-book while carrying out the recommendations of the committee by Orders in Council. Whatever doubts may exist as to the delay which has taken place there can be none as to the thorough nature of the work of the committee. Its findings are in the main careful and judicial and no one who has followed the minutes of evidence with attention can avoid the conclusion that the members are in possession of the smallest necessary details of the subject. While the old Vaccination Acts were in force, under which public vaccination was performed at "stations" and at stated intervals, the total cost for England and Wales has fallen gradually from £112,942 in 1872 to £72,665 in 1899. This decrease in expenditure was due to the faulty administration of the Acts by local bodies. In districts where there was active hostility to vaccination no compulsion was enforced and in districts where there was no active objection administration had become lax. The country was for seven years awaiting the final report of the Royal Commission of 1889, which did not finally present its report until 1896 and the effect was felt. The new Act was passed in 1898 and its first year of working ended on Lady Day, 1900. The cost of vaccination rose at once to £237,527 and in 1902 it reached £270,628. This enormous increase alarmed the boards of guardians and one-half of their number memorialised the Local Government Board on the subject. It had been realised that the working of the new Act would be very expensive but in drawing comparisons between the total cost of the procedures under the old Acts and the new one certain accidental features had not occurred to the minds of even those most conversant with the subject. No one knew, except the experts of the Local Government Board and the public vaccinators, how lamentably the vaccination of the country had declined and no one foresaw the inevitable result of that decline—the small-pox outbreak of 1902–03, with the equally inevitable rush for revaccination on the part of a frightened populace. If we compare the cost in 1872 with that in 1902 and make proper estimates for the increase of population and for the cost of public *re*vaccination, we shall find that the sum in the latter year is barely double that of the former; on the other hand, there is no question that the work, the time occupied, and the travelling expenses of the public vaccinator have all been increased fivefold by the changes in method introduced. Under the old system the "stations" were only opened on a limited number of days; an average number was three days each quarter, and (until compulsory vaccination was allowed to get into abeyance) the vaccinator was certain of some adequate returns, however distant his station might be. The travelling expenses were nominal; the time occupied was small, because 30 babies might be vaccinated in an hour if they were present. No clerical work beyond the entry of each case in the register and the filling in of the certificate was necessary. Matters are very different now; the actual operation of vaccination cannot be performed under 20 minutes; notice must be sent to the parent and the visit must be made by appointment within the hours of 9 A.M. and 4 P.M., however long the journey may be. The most trifling cause for refusal or postponement must be accepted and no extra payment is made or allowed for any extra journey.

Though it is true that a large number of boards of guardians did arrange fees with their vaccinators which afforded a poor average of remuneration for the enormous increase of work which was performed, the appendices to the report, when considered carefully, show how poor the pay has been. Half the boards of guardians in England and Wales have appealed to the Local Government Board for a reduction of the fees and yet the committee recommends the lowering of the *minimum* fees and trusts to the consideration of these very boards to offer a good average of stipend for the very careful and exacting work which is now demanded. The minimum fees paid under the Order of 1898 were 1*s.* for each child reported by the vaccination officer as unvaccinated by the time he or she attained four months of age and 5*s.* for each successful vaccination at the child's house or for each revaccination at the patient's own house. Many boards of guardians paid larger fees than these, granting 2*s.* for each unvaccinated child (technically known as fee (*a*)) and sums in excess of the minimum which were supposed to cover the large amount of unremunerative work. Under the committee's recommendations a system of "zone" minimum fees is to be established; thus fee (*a*) remains the same, while for successful vaccination within one mile of the vaccinator's house only 3*s.* can be claimed, 4*s.* for cases between one and two miles, and 5*s.* for over two miles. For work effected beyond three miles the vaccinators and their boards will have to make special terms. The fees for revaccination at the vaccinator's house will remain at the rate of 2*s.* 6*d.* The committee is careful to point out that it does not consider these figures as affording a sufficient remuneration in every case, and in districts where the population is scattered or where there is local opposition to the practice of vaccination consideration of these conditions should be, in its opinion, taken. In such districts it feels assured that boards of guardians will in the future be willing to pay higher fees than the minimum required by statute. It is difficult to feel the same ready confidence that all boards of guardians will display this liberality. The committee itself emphasises the fact that the boards and the public are imperfectly acquainted with the duties which the public vaccinators are now called upon to perform, and there is little likelihood that the mere issue of this report will tend greatly to leaven the large mass of this ignorance, while the fact that the minimum fees have been lowered by the recommendations will be readily grasped and as readily acted on. No question exists in the minds of the public health department of the Local Government Board and of the committee of inquiry that the standard of vaccination has risen under the present working to a highly efficient level. The proportion of infantile vaccination has reached a point promising real safety to the country, the "insertional results," with their increased protective value, have been greatly enhanced when compared with those of the "arm-to-arm" operation, while the confidence in the quality of the lymph and in the methods of the operation induced in the public mind has admittedly been a factor which has assisted to swell the expenses. The evidence of one witness was accepted in a curiously phrased paragraph by the committee as to the effect of this confidence. For since the passing of the Act of 1898 an increasing number of persons of superior position and means who formerly would have called in their private medical attendants have availed themselves of the services of the public vaccinator. The varied reasons for this change in opinion are carefully brought out in Mr. MAUDE's evidence[1] and are summarised in the report, which does not, as it should, condemn this abuse of public vaccination.

Thus while the report acknowledges the excellence of the work done and the great labour involved in its performance, the profound knowledge of the question of vaccination, clearly possessed by the authorities in Whitehall, must lead them to appreciate the difference between first-rate and inferior work on the part of their vaccinators. It was admitted on all hands that the work effected under the old Acts was not always first class; it may be asked, does any business-like community expect first-class work from men whose remuneration is cut down to the lowest point? A better standard of work exacted and a better standard of pay provided promptly produced a higher class of result. The work and the pay stand in the position of the premisses to a syllogism and every logician knows the effect on the result if either premiss is disturbed. It is therefore with regret that we discover that the only real practical outcome of the committee's labours is a recommendation of the reduction of the vaccinators' fees. The reduction of fees proposed is based on the assumption that the urban vaccinators have been over-paid when receiving the minimum fee of 5*s.*, while the committee recognises the hardship inflicted on many rural officials who have had to travel enormous distances for exiguous fees per journey. How small these fees were under the old rates of pay is abundantly illustrated by some of the tables prepared by witnesses. One union is found paying an average of 6*d.* per mile for the work done, there being an average mileage per case vaccinated of 12 miles, and the minimum fee of 5*s.* for successful cases. When we remember that this work has to be done by previous appointment the insufficiency of the remuneration is obvious. The committee states (§ 83) its opinion that having regard to the work done the remuneration of public vaccinators since the Act of 1898 came into force has in many cases not been excessive, particularly in country districts. At the same time it considers that the fees may be reduced without hardship if the provisions of the Order are made more elastic, but the changes in the direction of elasticity appear very slight, in fact to consist in the proviso that if vaccination is refused or deferred for any reason except that of the certified ill-health of the child the vaccinator need pay no further visit, as he has to do at present, but the child must be taken to the vaccinator's house. The relief in other directions of work is purely nominal and is in no degree likely to make up for the curtailed emoluments. The suggested change that public vaccinators should have the same fixity of tenure of office as other Poor-law officers have will be welcomed by those officials whose association has long striven for this security. The law by which a public vaccinator's contract may be terminated at 28 days' notice by his board of guardians has been a grave injustice, as it has frequently been employed by boards to cut down the fees to the legal minimum by the threat of immediate dismissal if the terms are not accepted. The proposals of this report will not be received with any satisfaction by the urban vaccinators and many of the rural officers will have a hard fight to secure an adequate return for their important labours. We trust that the Local Government Board will accord to them proper support when the time comes. Since the advisers of that Board obviously rate good vaccination at its proper value it is to be regretted that the committee has not had the courage at this appropriate juncture to recommend that the payment for this work should be debited to other accounts than those of small boards of guardians whose purview in many matters (and especially in that of vaccination) is frequently narrow and prejudiced.

The Teaching of Hygiene and Temperance in Elementary Schools.

AN important conference of medical practitioners was held at the Examination Hall, Victoria Embankment, on March 24th, Sir WILLIAM H. BROADBENT being in the chair, to discuss the question of promoting the teaching of hygiene and temperance in elementary schools.[1] The chairman, in his opening speech, pointed out that there could be no doubt of the necessity of such instruction and that therefore the training of teachers and the provision of suitable books were the first considerations. Lord LONDONDERRY, President of the Board of Education, in receiving a largely attended deputation of medical men pointing out the importance of this matter, while expressing sympathy with its objects declared that the teachers in elementary schools were not as yet qualified to give instruction in hygiene. Sir VICTOR HORSLEY stated at the meeting that the petition from which the movement originated (which was signed by nearly 15,000 medical practitioners) had been circulated widely and had received very favourable consideration from a large number of educational authorities in different parts of the country, but in the meantime the Board of Education had published a memorandum by Sir MICHAEL FOSTER criticising adversely certain syllabuses in use among teachers for their guidance in the instruction of children in these subjects. According to Sir VICTOR HORSLEY these criticisms were so misleading that a protest had been drawn up and forwarded to the Board of Education. In conclusion Sir VICTOR HORSLEY stated that "the object of the present medical movement was to secure that the subjects of bodily health and vigour and of healthy homes should receive as much attention at least as geography and history." With these objects and with the adequate instruction of both teachers and pupils in the fundamental principles of hygiene, both personal and domestic, we are in complete and absolute sympathy, as the results can only be beneficial, but the two documents referred to, the memorandum of Sir MICHAEL FOSTER and the protest signed by a number of well-known medical practitioners, are both of a nature to require comment.

---

[1] Minutes of Evidence, p. 61, Q. 1514 et seq.

[1] See THE LANCET, April 1st, p. 881.

At the outset it may be admitted that Sir MICHAEL FOSTER'S memorandum is a misleading and unfortunate document—misleading in virtue of its incompleteness and somewhat unnecessary technicality and unfortunate in its liability to misconstruction. The memorandum as published by the Board of Education with extracts from "certain" syllabuses employed in the teaching of hygiene and temperance is incomplete, since the syllabuses themselves are not included and no reference is given to enable them to be identified, whilst the attempt to define in scientific language certain terms which have a more or less indefinite significance as used popularly, such as "nourishing" and "intoxicating," is far from satisfactory. On the other hand, although we are in the main in accord with the letter of protest addressed to Lord LONDONDERRY, it is, perhaps, a little unnecessarily severe in its castigation of Sir MICHAEL FOSTER'S memorandum. The obvious intention of Sir MICHAEL FOSTER is to protest against the too sweeping assertions sometimes made in relation to the actions of alcohol and to the dogmatic application of the teachings of physiology to everyday problems without careful consideration of all the factors concerned. To give an example, the following paragraph is quoted from one of the syllabuses: "A poison is something antagonistic to life. Food supports life; poison destroys life. Alcohol is defined as a poison because it acts in a contrary way to food." So slipshod and inaccurate a definition merits the criticism which it receives from Sir MICHAEL FOSTER who states: "If we take into consideration *all* variations in the conditions of the body and not those of 'health' alone it may safely be stated that there is no substance which in a certain dose may not, under certain conditions, be taken into the body with beneficial effects. The qualities leading a substance to be called a poison are relative, not absolute." Unfortunately, Sir MICHAEL FOSTER, in order to illustrate the truth of this important proposition, points out that substances like oxygen and water, which are admittedly essentials of life, may under certain artificial conditions become injurious, without sufficient explanation of the artificiality of those conditions, with the result that misconception is very liable to occur, as is shown by the remarkably ingenuous note of the Board on this matter to the effect that no reference is made (in the syllabuses) to "any dangerous properties of oxygen." Again, Sir MICHAEL FOSTER quite rightly objects to statements such as the following extracted from the syllabuses: "We need not then be afraid to speak of alcohol by its proper designation as a poison. In small quantities it does not kill, but the same thing may be said of strychnine, arsenic, and other poisons. We may sum it up thus: in considerable quantities alcohol will kill, in smaller doses it does injury corresponding to the amount taken"; and again, "Alcohol within the body is always our foe and never our friend." The inconsequence of such statements when examined critically is obvious, but Sir MICHAEL FOSTER again invites misconstruction by pointing to the injurious effects of distilled water on tissues and stating that the argument used in the syllabuses might with equal justice be employed in favour of total abstinence from distilled water, a statement which is apt to suggest that the injurious effects of alcohol and distilled water are of like character and degree. There can be little doubt that in the end both Sir MICHAEL FOSTER and his critics have practically the same objects at heart since Sir MICHAEL FOSTER in his memorandum writes: "There ought to be no difficulty in teaching even young children hygienic duties in a broad way, basing the teaching on the results of common experience, using physiological science, and then only simple and general physiological truths, as illustrating those results and showing the sound basis on which the teaching rests. But to teach hygiene as is proposed in the syllabuses submitted, in the form of deductions from special physiological observations often of a doubtful character, can only be productive of harm."

It is earnestly to be hoped that one outcome of the matter may be a comprehensive discussion of the aims and the scope of the teaching of hygiene in elementary schools and the publication of an authoritative and explicit syllabus of such instruction by a committee of hygienists, physiologists, and educationists, if possible under the auspices of the Board of Education. A proper syllabus of this kind dealing with the subject in a broad way and not confined to the uses and abuses of alcohol but including reference to the injurious effects of other substances in excess, including tea, is, as stated by Sir LAUDER BRUNTON, one of the signatories of the protest, in a footnote appended to it, a pressing need at the present time.

King Edward's Hospital Fund for London.

THE proceedings of the annual meeting of the General Council of KING EDWARD'S Hospital Fund for London, of which we gave a full report last week, are in many respects calculated to exert an abiding influence alike upon the hospital administration and upon the medical education of the metropolis. It has long been evident to all interested in the question that the complete independence of the London hospitals and the active competition for support in which they are frequently engaged are not conducive either to efficiency or to economy, and the founders of the Metropolitan Hospital Sunday Fund early entertained a hope that its influence might be useful in promoting a harmonious adjustment of the claims of contending charities and in diminishing rivalries which were by no means certain to issue in the survival of the fittest. It soon became manifest, however, that neither the Sunday Fund nor the Saturday Fund was so organised as to exert any considerable authority over hospital management or to deal with its difficulties in any effective manner; and hence, excepting in a very few instances, the functions of the distribution committees became arithmetical rather than judicial. The establishment of King Edward's Fund was the signal for a new departure in this respect; not only because its committees were so constituted as to command an increased degree of public confidence, but also because their investigations into questions of claims and merits were more effective than any which had previously been attempted. A society actively supported by Royal patronage, wielding the power of the purse to a large and constantly increasing extent, and commanding the services of many persons eminent in the clerical, legal, and medical professions, was a body qualified to form conclusions which could not be disregarded with impunity. A hospital on which such a body bestowed damaging criticism was hardly likely to succeed in an appeal from that criticism either to the general public, or to the more restricted number of its previous supporters, and opinion was gradually taught to look for, and to acquiesce in, the decisions of the Fund, and to recognise that hospital administration is a matter demanding the knowledge of experts and capable of being tested by rules which they are able to apply. The hands of the administrators of the older funds were materially strengthened by the trust which the public soon learned to repose in the new one; hence we have just seen that a diminution of the grant from the Sunday Fund to the National Hospital for the Paralysed and Epileptic on the score of undue expenditure upon in-patients, instead of producing the indignant protests which it would probably have called forth only a few years ago, was speedily followed by careful and painstaking inquiry upon the part of the committee and by reforms which, without any impairment of efficiency, effected a saving of £2000 within a year. Hospital boards and officials have been compelled to recognise their responsibility, not only to their subscribers but to the public, for the proper and judicious expenditure of the large sums annually committed to their stewardship and to see that good intentions furnish no defence against well-founded charges of undue costliness of management or of undue carelessness in administration.

The most important question raised in the report of King Edward's Fund for the past year, and one which was dwelt upon by the Prince of Wales in his speech from the chair, had reference to the propriety of the assistance hitherto given by many hospitals to the medical schools connected with them. The question, as our readers will remember, was originally raised by the antivivisection society or societies which, like a well-known scriptural character, spoke "not because they cared for the poor" but under the influence of widely different motives; and it is probable that the first and not unnatural effect of their agitation was to arouse a feeling of opposition on the part of many of the genuine friends of hospitals and a determination to support the school subsidies against their assailants. Lord Stanley, as treasurer of the London Hospital, has informed the public that his committee tested the feeling of its supporters by inviting them to earmark their contributions as applicable, at the discretion of the committee, either to the patients or to the school and that the contributions thus earmarked within a week amounted to twice as much as the largest sum ever given by the hospital to the school within a year. But the question was too important to be disposed of in this summary manner and the governing body of King Edward's Fund appointed a special committee to inquire into, and to report upon, it, a committee consisting of Sir Edward Fry, the Bishop of Stepney, and Lord Welby, to which Mr. Danvers Power, the chairman of the committee of the National Hospital for the Paralysed and Epileptic, consented to act as honorary secretary. The report of this committee set forth that of the 12 hospitals which have medical schools at least eight had contributed from their funds to the cost of medical education, and proceeded to declare that the committee "do not find that any special considerations have been advanced in justification of the expenditure by the hospitals on the schools." Whatever differences of opinion may exist with regard to the soundness of this conclusion, it is at least certain that the governing body of the King's Fund intends to act upon it, and that the payment of subsidies to the schools, apart altogether from the grounds urged by the first opponents of the practice, will for the future be systematically discouraged by the Fund. The expressions used by the Prince of Wales, although extremely moderate, were none the less decided. He said that, in consequence of the date of the report, the hospitals could not act upon it during the present year in such a way as to clear their accounts of the school charges and that he hoped that the authorities of the Fund would be regarded as acting reasonably if they deferred dealing with the question until the year 1906 and thus gave the hospitals nine months in which to consider their position. After the lapse of that time it would be required of them that the whole of the grants from the King's Fund should be applied to the relief of the poor, so that the contributors to that Fund might have complete assurance that their money was employed in no other manner. It may be presumed, we suppose, that the Fund would not raise any objection to the exercise of such a discretion as that which Lord Stanley's committee has asked for and obtained from a certain section of its supporters.

But the aspect under which the Prince of Wales's declaration will be chiefly interesting to the medical profession, and one upon which His Royal Highness himself laid stress, is that of the probable effect of the change upon medical education. The Prince of Wales displayed complete acquaintance with the results of conducting that education, or at least the preliminary portions of it, in a number of small and insufficiently equipped schools, and he spoke hopefully of the benefits which might be expected to arise from the transference of the preliminary and intermediate subjects to an institution specially organised for the purpose and as far as possible of a university character. He expressed his pleasure in the knowledge that the Senate of the University of London had already put forward a scheme for the establishment of an Institute of Medical Sciences in connexion with the University, and he appealed to the public to supply the funds necessary for this purpose, making especial reference to the recent generous donation from Mr. Beit. It is well known that members of the Royal Family do not speak in public upon technical subjects save after consultation with competent advisers and we may therefore conclude that His Royal Highness's expectations of improved medical education are shared by many members of the profession, as they are by ourselves. There will, no doubt, be a period of transition, during which the old order will be weakened, while the new will not yet be in a position to meet all the demands likely to be made upon it, but difficulties of this kind are inseparable from change and must not be suffered to diminish our perception of the benefits which the change will ultimately secure.

Annotations.

"Ne quid nimis."

THE PURITY OF WATERCRESS AND WATERCRESS BEDS.

Suspicion has more than once been entertained that watercress has given rise to an outbreak of enteric fever and there is little doubt that watercress is not infrequently cultivated in an environment which is liable to specific pollution. It would appear from a report recently issued by the London County Council and drawn up by the medical officer of the Council, Sir Shirley Murphy, that watercress may well be the carrier of disease, since at any rate not all the known beds situated within some 50 miles of the county of London and supplying the London market exist under conditions of strict sanitary requirement. So far, however, the evidence that watercress can be a source of danger because it acts as a carrier of sewage-contaminated water has not been thoroughly conclusive. It is at any rate obviously desirable that watercress should not be allowed to be cultivated in water which is grossly polluted or which shows a worse degree of impurity than does an ordinary drinking water-supply. As a result of a topographical inquiry made over the area just mentioned by the county council inspectors the best beds were found, generally speaking, upon a bottom of hard clean gravel. Such beds are regularly cleansed and in some instances are occasionally treated with lime in order to destroy organisms deemed to be injurious to the watercress. On the other hand, there were beds found in sluggish streams or backwaters having muddy bottoms and receiving the drainage of grazing lands. The water-supply was found to be derived from various sources, such as rivers, canals, natural springs, and artesian wells. The causes of pollution were found to be many and various. Surface drainage from grazing lands is often allowed to enter the beds and in some instances house drainage and the drainage from trade premises are permitted to aggravate the mischief caused by want of proper cleansing and the unchecked growth of rank vegetation. Dr. Frank Clowes, chemist to the Council, examined 129 samples of water from watercress beds and his examination led him to classify the results into four groups. In the first group, including 53 samples, the purity of the water as regards nitrogenous organic matter was about the same as that of Thames-derived filtered water. 47 samples in the second group were found to contain the same nitrogenous equivalent as the water of the Thames above the water companies' intakes. The third group included 22 samples in which the nitrogenous organic matter was excessive and the fourth group included certain samples in which the nitrogenous organic matter was very excessive. In the third and fourth groups, in fact, there can be little doubt that the samples were polluted with sewage. The bacteriological inquiry carried out by Dr. A. C. Houston confirmed the evidence yielded by topographical investigation. The best waters contained no "coli-like" microbes of any sort, and the least satisfactory waters contained from 1000 to 10,000 "coli-like" microbes per cubic centimetre and yielded positive results with the bacillus enteritidis sporogenes test. On the basis of the bacillus coli test the best waters were from 1 to 10 million times purer than the least satisfactory waters. Generally speaking, Dr. Houston finds that watercress reflects bacteriologically its aqueous environment—that is, the more polluted the water the less pure is the watercress and the purer the water the cleaner is likely to be the watercress. The importance of thoroughly washing the watercress is shown by the fact that the final as compared with the first washing of impure watercress was usually found to contain a much smaller proportion of objectionable microbes. The results seem to indicate, however, that no ordinary amount of washing could be relied on to remove from watercress grown in polluted waters all undesirable microbes. This may be due either to bacteria so firmly adhering to the exterior of the plant as to resist being swept away during the washing process or to the watercress harbouring microbes within its structure or to a combination of these causes. In regard to standards applicable to the water "feeding" watercress beds Dr. Houston thinks that the imposition of drinking water standards would press rather heavily on the watercress industry. He suggests a broad classification in regard to bacteriological purity on the lines already tentatively brought forward in his reports to the Local Government Board and to the Royal Commission on Sewage Disposal. It is evident that some control in this matter is called for, since the consumption of watercress amounts in London to as much as 1500 tons per annum. Nor is its consumption confined to the poorer classes who use it as a pleasant adjunct to bread and butter, for it is frequently used as a salad with game and poultry.

"A NEW FOOD FOR USE IN TYPHOID AND OTHER FEVERS."

We have received a copy of a pamphlet bearing the above title, written by Dr. J. W. Springthorpe, physician to the Melbourne Hospital, and reprinted from the *Australasian Medical Journal*, in which the writer draws attention to the disadvantages which he considers that milk possesses as a food. He is of opinion that it but imperfectly fulfils the requirements of a food during fever. Professor Voit has shown that three and a half pints of milk of good quality (from 8 to 10 per cent. of cream), though satisfying a healthy idle adult, are deficient in the albumin required, and while containing twice the fat are wanting in carbohydrates to the extent of two-thirds of that contained in an ideal diet. A diet for use in cases of fever should contain more carbohydrates and less albumin than an ordinary diet and should be free from fat; therefore Dr. Springthorpe argues that even with the addition of some form of animal broth the quantity of milk recommended by physicians must fail to meet the requirements of a patient suffering from continued fever. Further, he maintains that though a fluid food in the mouth, milk becomes a more or less solid food in the stomach—the undigested curd represents so much less of albumin, whilst the curds themselves are a frequent cause of rise of temperature, restlessness, diarrhœa, and "other aggravations of an already serious if not dangerous condition." He admits, however, that curdling may be diminished by appropriate dilution and admixture Milk, too, s stated to be a food very likely to ferment; hence distension and all the discomforts and dangers which follow therefrom. After enumerating other disadvantages which he alleges that milk possesses as a food in cases of fever he proceeds to suggest a substitute. He draws attention to the fact that whilst testing the suitability of various food-stuffs for the growth of Eberth's bacillus M. de Bavay discovered that a sterilised hopped malt extract was superior to either broth or milk in its resisting power, there being absolutely no growth whatever when typhoid bacilli were introduced into it. Analysis showed that it consisted of soluble carbohydrates, peptones, parapeptones, and amides, a small proportion of ash, rich in phosphoric and lactic acid, and the extract of hops. The malt extract was tested practically during an epidemic of typhoid fever and Dr. Springthorpe came to the following conclusions: 1. That sterilised hopped malt extract may be given as a food in place of milk in the treatment of typhoid fever. 2. That the extract has many advantages over milk. Thus, its composition may be made definite; it is easy to keep and to administer; there is no risk of its becoming sour; there is no need of peptonising or of adding alkalies or effervescents; and it can be taken with acids. 3. That "in many ways it meets the requirements of the case better than milk." Thus, the active principles are pre-digested, the carbohydrates predominate, and fat is absent. 4. It exerts upon the disease a beneficial influence which is not found in the case of milk. In an appendix to this communication directions are given for the preparation of the extract. The results obtained by Dr. Springthorpe are certainly interesting and the preparation merits further trial.

INCOMPATIBILITY IN THEORY AND PRACTICE.

IN an interesting paper (published in the *Pharmaceutical Journal* of Feb. 18th) Mr. J. P. Gilmore has communicated his views on incompatibles. The various cases of incompatibility are grouped by the author under their main headings, due severally to the production of an insoluble substance, to theoretical chemical disagreement without detriment to therapeutic effect, and to the formation of products the medicinal properties of which are dissimilar to those presumably required by the prescriber. It will at once be conceded that the last case alone, as cited by Mr. Gilmore, deserves serious consideration. Many drugs act best in the solid form as, for instance, the salts of bismuth, while the acid in the gastric juice frequently dissolves many insoluble compounds. There are a few cases in which absolute danger results from this class of incompatibles—e.g., where strychnine is totally precipitated from an alkaline solution, on standing, there is a great chance of the patient taking the greater part of the alkaloid in the last dose. Again, chemical disagreement has in certain cases been shown by long usage to be either an advantage or without deleterious effect. Thus prescribers daily gain satisfactory results from combinations of lead and opium, ergot and iron, digitalis and iron preparations, and ferrous iodide and mercuric chloride. In such cases there is generally no necessity for the dispenser to trouble the prescriber. Indeed, many cases of incompatibility are so designed by the prescriber. An instance illustrating this point has been recorded of a laryngeal paint containing cocaine hydrochloride, sodium bicarbonate, mucilage of acacia, and water. Advantage is here taken of the fact that the anæsthetic action of cocaine on the mucous membrane is more energetic in the presence of sodium bicarbonate. But when chemical incompatibility leads to the formation of products of different therapeutic value—e.g., a combination of strychnine and chloral hydrate to which Mr. Gilmore refers in his paper—the case assumes an importance that cannot be over-estimated. The difficulty is increased from two causes, the unfamiliarity of many prescribers with the interactions of various drugs and the general lack of therapeutic knowledge among dispensers. Hence the dispenser, unless he has had long experience, is often at a loss to know whether certain combinations are harmful or not. In such cases he should not hesitate to consult the prescriber. Two instances of incompatible combinations evidently due to error are given by Mr. Gilmore: the first a diarrhœa mixture containing diluted sulphuric acid with chalk mixture; and the second a lotion containing cocaine hydrochloride and sodium bicarbonate in water, the directions being to filter through paper. In the latter case the operation of filtering would naturally remove the cocaine from solution. The subject of incompatibility is difficult to deal with, not so much from the frequency with which usually harmless incompatible substances are prescribed together but from the risk that either in ignorance of the harmfulness of a particular combination or with a desire on the part of the pharmacist not to trouble the prescriber unnecessarily fatal results may occasionally follow from the dispensing of an incompatible prescription as written. The wide use of the newer synthetic remedies undoubtedly increases the risk, though it will be materially reduced as their various actions become better known. It would seem desirable that in the future the scope of pharmacy and materia medica might be widened in the preliminary medical examinations, while dispensers should be encouraged to understand more of the physiological and therapeutic action of the remedies which they compound. In the meantime a mutual confidence between prescriber and dispenser cannot but be of benefit to the patient when unlooked-for difficulties arise.

GONORRHŒAL POLYARTHRITIS IN THE PUERPERIUM.

IT is not sufficiently recognised that the puerperium may waken into activity a pre-existing gonorrhœal infection and give rise to a condition which may be mistaken for puerperal fever. At the meeting of the Société Médicale des Hôpitaux of Paris on Dec. 23rd, 1904, M. Mosny and M. Beaufumé reported the following case. A married woman, aged 28 years, was delivered normally of her first child on Jan. 24th, 1904. On the fourth day of the puerperium the temperature rose to 104° F., which was attributed to influenza. On the fifth day the temperature was again normal but on the sixth it rose again to 100·8°. During the rest of the time she was in hospital it remained normal. There were no other symptoms. She left hospital against advice on Feb. 2nd. On the 5th she had slight pains in the left shoulder and elbow and perspired abundantly at night. On the following day the left knee was affected and then the left wrist. She was readmitted on the 10th. When examined on the 11th she complained of pains in the joints. The right elbow and wrist-joints and the metatarso-phalangeal joint of the right great toe were swollen, red, and painful. The left knee was very swollen; it was not the seat of much spontaneous pain but movements were so painful as to be impossible. Vaginal examination showed only a slight laceration of the cervix and a little leucorrhœa. Salicylate of methyl was applied to the joints and one and a half grammes of quinine were given daily. On the following day the swelling of most of the joints had subsided but the left knee was still more swollen. On the 18th it was aspirated and yielded 40 cubic centimetres of greenish sero-purulent fluid containing ordinary polynuclear cells. Microscopic examination did not show either streptococci or gonococci. Cultures on gelose and bouillon were negative but some gonococci were found in the pus which was deposited at the bottom of the tube of bouillon. Cultures on serum and on blood and gelose yielded the gonococcus in pure culture. The gonococcus could not be found in the vaginal mucus or in the urethra. For a long time before marriage the patient had suffered from abundant leucorrhœa after menstruation. For a year the discharge had been thick and yellowish and stained her linen. On the 18th the left knee was enveloped in cotton wool, tightly bandaged, and placed in a splint. Salicylate of sodium was given in daily doses of eight grammes and the dose was gradually diminished. This treatment was not efficacious and therefore on March 9th salophen in doses of five grammes daily was substituted for the salicylate. At this time the muscles of the left lower limb were much atrophied. The salophen also failed. All medication was stopped on the 25th and only the immobilisation and compression of the knee were maintained. On April 5th the temperature became normal but the knee remained tender. On the 23rd treatment by immobilisation and compression was changed to massage and passive movements. The atrophy was so great that the circumferences of the thigh and the leg were two centimetres less than on the other side; on the other hand, the circumference of the knee was from two to three centimetres greater. Improvement took place and on May 14th movements of the knee could be performed without pain. On the 27th the patient was discharged able to walk but the muscular atrophy was undiminished. The important point in the case is the complete latency of the gonorrhœal infection until it was stimulated into activity by the puerperium. It is also noteworthy that the history did not disclose the existence of gonorrhœa and no signs of it were found at the pelvic examination. Moreover, the child did not suffer from ophthalmia. The gonococcic arthritis, therefore, simulated the usual form of puerperal arthritis, the streptococcic. When the arthritis took a mono-articular phase confusion with puerperal arthritis was no longer possible. The case shows the necessity of careful bacteriological examination in the diagnosis of gonorrhœal arthritis.

THE MORALITY OF THE DUTIES ON SPIRITS.

ON Monday next the Chancellor of the Exchequer will present the Budget in the House of Commons and it is generally known that the financial statement in regard to the year's revenue is satisfactory and that there will be a balance of some millions to the good. An interesting feature of the year's revenue, we learn, is that despite this surplus the income derived from the taxation of alcoholic liquors has very appreciably declined. This, of course, means a diminished consumption of wines and spirits which may be traced, perhaps, to a moral improvement in the nation's temper or, as is more probable, to a reduced spending capacity of the individual brought about by commercial depression. Personally, we should welcome a falling off in the revenue from alcoholic liquors if such a circumstance only helped to remove the reproach, as the forthcoming Budget appears to do, that our finances are largely supported by the nation's indulgence in alcohol. The argument, moreover, that because wines and spirits are an important source of revenue it would be inconvenient from a purely fiscal point of view to interfere with the activity and the custom of the trade would receive a healthy set-back. It is notorious that when Chancellors of the Exchequer have had their attention drawn to the desirability of the Government exercising control over the purity and the quality of excisable liquors they have evaded the question, fearful lest any action should interfere with a substantial source of revenue. The Government or its officials only care to collect the tax regardless entirely of the quality or the wholesomeness of the spirituous drink upon which that tax is imposed. There is thus no discrimination made between the genuinely described and the falsely described. In a word, all spirits are merely alcohol from the fiscal point of view and all question as to the materials from which the spirit has been made is completely ignored—that is to say, the tax is the same whether the foundation of the spirit has been malt, grapes, corn, molasses, sugar, potatoes, or, in fact, anything from which alcohol can be made, and the category may include a list of very undesirable materials. Surely this uncompromising method of taxation is a grave injustice to the consumer who, after all, bears the tax. Is it logical, is it just, to impose upon the consumer the same amount of tax on the genuine article as upon that which is incorrectly described? The principle that the consumer should be completely in the dark as to the genuineness of the article upon which he pays a heavy tax is surely unsound. It is all very well from the tax-gatherer's point of view but morally it is wrong. The consumer is entitled to get genuine tea, coffee, or cocoa when he asks for them and he expects to participate in the tax in accordance with the adjustment of the customs tariff, but he naturally would resent having to bear the same rate of imposition on mixtures of tea, coffee, or cocoa. There is a duty on cocoa of 2*d.* per pound which, of course, the consumer indirectly pays, but there is no duty on starch. When, however, a mixture of cocoa and starch is sold to him as cocoa he is cheated and he has a remedy in the Sale of Food and Drugs Act. He is similarly cheated when on demanding a grape spirit (i.e., brandy) or a malt spirit (i.e., whisky) he is supplied with grain spirit or patent spirit which is obviously not of the nature, quality, or substance of the article demanded. Yet whatever spirit he may happen to be supplied with he pays the same duty and the reply of the Government is laconic enough, "It is all alcohol." Such an answer may satisfy fiscal needs but it is distinctly detrimental to the welfare and the health of the community. It is, in fact, time that the public received some consideration and protection in this matter and it is anomalous that a system of taxation should exist which deals with the genuine article on the same terms and level as it does with an article which is practically falsely described. It amounts to deriving revenue from a species of fraud.

THE INSTRUCTION OF THE YOUNG WITH REGARD TO VENEREAL DISEASE.

WE have before us a series of five lectures[1] delivered to the students of the University of Copenhagen by Professor Erik Pontoppidan with a view to instruct a general audience of young men, not necessarily intended for the medical profession, as to the significance and the prevention of venereal disease. These lectures were first given under the auspices of the International Conference "Pour la Prophylaxie Sanitaire et Morale" held at Brussels in 1899 and they have since been repeated in the autumns of 1900, 1901, and 1902, no doubt with the object of attracting the attention of junior students at the beginning of the academic year. The lecturer has aimed at imparting to his audience a measure of scientific knowledge of the hygienic aspect of venereal infection corresponding to the instruction sought to be made general with regard to tuberculosis during recent years. He explains at some length the nature and the causes of venereal disorders and the outlines of the treatment necessary to eradicate them from the infected person, dwelling upon the consequences to the individual of the neglect of adequate measures and upon the results to the community of the unchecked dissemination of the evil. This neglect, he points out, is due to ignorance and in a great measure also to other causes such as the desire for secrecy and he urges fuller knowledge accompanied by more open recognition of the danger together with prevention not only by medical and sanitary precautions but also by the setting up of pure and healthy ideals of life. The subject is one of great importance and the question as to how far it can be broached publicly and discussed with a view to the amelioration of existing conditions is in itself one upon which diverse opinions are held. Of the prevailing ignorance none can doubt. In the more intelligent class from which Professor Pontoppidan's hearers were drawn it leads to medical aid being sought either not at all or too late and to a want of perseverance which is equally undesirable. With regard to the ignorance of the less educated classes we note that the lecturer refers to the existence in Denmark of a hideous superstition, with which medical men and lawyers practising in criminal courts are familiar in this country, that sexual intercourse with a virgin, or the passing on of infection to a child, will cure venereal disease. When such ideas as this require to be stamped out it can hardly be denied that more extended knowledge is desirable; and when the desirability of discussing such topics with the young is disputed it must be borne in mind that this, as a rule, amounts to the substitution of sound and accurate knowledge imparted by one in the position of a teacher for such information as his hearers would otherwise gather from untrustworthy and tainted sources and would disseminate in unhealthy conversation among themselves. With reference to the lives led by young men in universities Professor Pontoppidan refers with approval to the influence of athleticism in the discouragement of sexual indulgence and pays a high, and let us hope deserved, compliment to English universities and to the attitude towards licentious talking and living which he finds prevailing in them. The conditions existing in the British army, on the other hand, fill him with surprise and horror which he does not disguise and he would no doubt point to the rank and file of our battalions as a suitable field for the development of knowledge as a prophylactic. His lectures, however, are for a different class and we would recommend their perusal and the consideration of the course suggested in them by teachers of those who when instructed are most likely to be able to influence others, if not by precept at least by their example.

---

[1] What Venereal Diseases Mean and How to Prevent Them. By Professor Erik Pontoppidan, M.D., chief physician to the Western (Lock) Hospital, Copenhagen. Translated by W. Jessen. London: John Bale, Sons, and Danielsson, Limited. 1905. Pp. 79. Price 2*s.* net.

AN INTERNATIONAL MEDICAL ASSOCIATION AGAINST WAR.

ON March 21st there assembled at the house of Dr. Rivière, in Paris, more than 200 medical men. The object of the meeting was the association of medical men for the purpose of doing all in their power to do away with war. It was decided to found an International Medical Association against War and it was proposed to hold a congress on the subject in two years' time. Those present were constituted the committee of the movement and officers were elected as follows. President: Dr. Rivière. Vice-Presidents: Dr. Philippeau, Dr. Suarez de Mendoza, and Dr. Th. Mende Ernst. General Secretary: Dr. Mazery. Secretaries: Dr. Pokinotoff, Dr. Antonelli, Dr. Cree, Dr. de Torres Mendiola, Dr. de Castro Soffia, and Dr. Cogrel. Treasurer: Dr. Marechal. Delegated secretaries: Dr. Mazery, Dr. Cree, and Dr. Cogrel. Dr. Rivière, who opened the proceedings in an able discourse, reminded his hearers of the horrors of war; he pointed out how the North Sea incident showed very well what arbitration could do and argued that medical men who were so intimately acquainted with human misery, both physical and moral, were by that very fact the most fitted of the community to collaborate in the great work of substituting arbitration for war. Dr. Rivière has set up a high ideal but there is no one who will not earnestly hope that this ideal may be realised in the near future. Even though war, as it undoubtedly does do, calls forth the finest qualities of human nature, the hideously effective action of modern methods of destruction sickens the heart. And its effects are not limited to the battlefield. As our great master of English prose said (he is speaking of the distress and anxiety with which the casualty lists from Flanders were studied in this country after Waterloo): "If such an interest could be felt in our country and about a battle where but twenty thousand of our people were engaged, think of the condition of Europe for 20 years before, where people were fighting, not by thousands, but by millions; each one of whom as he struck his enemy wounded horribly some other innocent heart far away."

DANGERS TO THE OPERATOR FROM THE X RAYS.

THOUGH the injuries inflicted on the patient in the use of the x rays have been repeatedly recorded little attention has been directed to the dangers to the operator. However, some alarmist reports come from America and if at present the evidence is not sufficient to accept them absolutely at least a good case is made out for greater care in using the rays. According to a recent editorial article in the *Medical News* of New York Dr. Tilden Brown has demonstrated absence of spermatozoa (azoospermia) in the semen of a number of patients and physicians who had spent more or less time exposed to the x rays. They, however, were not conscious of any loss of potency. These observations are supported by certain experiments made in Germany. About 18 months ago Albers-Schönberg found that if the abdominal surface of male guinea-pigs or rabbits was exposed for a prolonged time to the x rays the animals became sterile but their potency was unimpaired. This sterility was due to the development of azoospermia, which was shown by Seldin to depend on the disappearance of the epithelium of the seminiferous tubes. Recently Hulberstaedter has described experiments which show that the ovary is even more susceptible to the action of the rays than is the testis. In the *Boston Medical and Surgical Journal* of March 9th Dr. H. W. van Allen has discussed the dangers to the operator from exposure to the x rays and their prophylaxis. He has reported seven cases in which men were exposed to the action of the x rays in the genital region with the production of more or less dermatitis. The following is an outline of these cases:—1. 12 exposures, the last four months ago. Spermatozoa normal. 2. 12 exposures, the last a year ago. Spermatozoa normal. 3. 35 exposures, the last five months ago. Spermatozoa absent. Sexual function apparently normal. Age 38 years. 4. Ten exposures a year ago. Spermatozoa normal. 5. 15 exposures four months ago. Spermatozoa absent. Age 56 years. 6. An x ray tube maker, aged 42 years, who had changed his occupation and not been exposed for six months. No spermatozoa. 7. 45 exposures, last one 14 months ago Spermatozoa absent. Age 40 years. The cases of azoospermia were not those in which the dermatitis was marked but the ones treated the longest. The observations led Dr. van Allen to look for other effects. He found that in x ray workers of experience the skin and its appendages first suffer. The nails and the hair are brittle and of slow growth. The skin is dry and of a yellowish hue which is almost characteristic. Indigestion, especially of the intestinal kind, is present. The workers complain of inability to concentrate their thoughts for any length of time and are drowsy, although many suffer from insomnia. Their disposition is somewhat irritable. They complain of an abnormal sensation of cold. Radiographs of the thinner parts of the body show premature sclerosis of the arteries. To prevent such effects Dr. van Allen recommends that the operator should be entirely removed from the x ray atmosphere. The whole apparatus except the tube should be in one room and the tube and the couch for the patient in an adjoining room. The wall separating the rooms should be covered with sheet lead not less than $\frac{1}{32}$nd of an inch thick. Through this should pass the wires to the tube. In the wall should be a peep-hole, which might be protected with the glass from which are made cut glass articles (containing as much as 20 per cent. of lead). Or the hole might be protected by means of two mirrors facing one another at an angle with the perpendicular of 45°, one covering the opening and the other above it. The silver-covered mirror would prevent the non-reflectable x rays from striking the operator but he could see by the ordinary rays of light reflected from the mirrors everything in the room. The mirror covering the opening could be depressed by means of a handle and the fluoroscope used to judge the tube and the character of the light which it gave off. The only objection to this plan is that fluoroscopy would be abolished but Dr. van Allen does not consider this a disadvantage, as he thinks that it is less trustworthy than radiography.

INEQUALITY OF THE PUPILS IN PLEURISY WITH EFFUSION.

INEQUALITY of the pupils in diseases of the chest has been recently described by French writers. In 1902 M. Souques reported three cases of inequality of the pupils in pulmonary tuberculosis.[1] He attributed the inequality to pleuritic thickening and adhesion which involved and paralysed the pupil-dilating fibres of the sympathetic as they passed out from the cord in the ramus communicans of the first dorsal nerve. More recently inequality of the pupils in diseases of the lungs and the pleuræ has been discussed by Dehérain.[2] The subject of inequality of the pupils in pleurisy with effusion is almost entirely new. All that Dehérain says of it is that "in four cases of tuberculous pleurisy with serous effusion inequality of the pupils was constant for several weeks." He says nothing of the nature or the degree of the inequality or of its relation to the quantity and the nature of the effusion. M. A. Chauffard and M. L. Laederich have contributed an important paper on Inequality of the Pupils in Pleurisy with Effusion to the *Archives Générales de Médecine* of March 7th, in which they throw considerable light on these and other points. In pleurisy with effusion they found inequality of the pupils in seven out of 17 cases—i.e., in 41 per cent. of the cases. The larger pupil was almost always on the side of the effusion. The inequality varied much from day to day, sometimes even disappearing on certain days to return later. It was never found after the effusion was completely absorbed. The inequality was always moderate and never attained the magnitude observed in diseases of the brain and the spinal cord; sometimes it was so slight that it had to be looked for carefully by exposing the eyes to equal amounts of light with a medium condition of accommodation. On looking at a very near object the inequality disappeared; the pupils contracted to their maximum extent and became equal. The seven cases in which the inequality was observed comprised one case of "cardiac pleurisy" and six of tuberculous pleurisy. The 10 negative cases consisted of six cases of tuberculous pleurisy, one case of hæmorrhagic pleurisy (probably cancerous), two cases of pleurisy following pneumonia, and one case of "cardiac pleurisy." In these 10 cases all degrees of effusion were observed. Comparing the positive and the negative cases no relation could be traced between the amount of the effusion or the presumed condition of the apex of the lung in the tuberculous cases and the inequality. Paracentesis thoracis, even when 1250 cubic centimetres of fluid were removed, had no effect on the inequality. Discussing the cause of the inequality M. Chauffard and M. Laederich do not accept the mechanical theory put forward by Dehérain, that it is due to pressure of enlarged lymphatic glands or of the effused fluid on the pupillary fibres of the sympathetic. The fact that it varies from day to day is opposed to the former theory and the fact that paracentesis does not affect it is opposed to the latter. The inequality seems to be a functional phenomenon. Its explanation appears to lie in the dictum of Schiff: "All peripheral sensory irritation causes dilatation of the pupil." Probably it is due to irritation of the branches of the vagus distributed to the lung on the affected side. The unilateral character of the phenomenon is explained by Pflüger's law: "Reflex movements are first manifested on the side of the irritation."

THE HEALTH OF MARGATE.

IN his report for the year 1904, Mr. Bertram Thornton, medical officer of health of Margate, draws attention to the healthiness of the town and the excellence of the water-supply. As is well known the population of Margate is liable to great variations on account of the immense influx of visitors during the summer months. The estimated population on which the birth-rate, the death-rate, and other numerical averages are based is computed yearly from the data obtained at the decennial census which is held in the month of March. In Margate the estimated population to the middle of 1904 was 24,263, but for a few weeks during the summer season the population probably exceeds 100,000. The birth-rate in the borough was 19·0 per 1000 and the corrected death-rate was 12·8 per 1000, both of them being below the corresponding averages of the last ten years; by excluding the deaths of visitors the general death-rate would be reduced to 10·7 per 1000. The water-supply from local sources had become so impregnated with salt (as much as 170 grains to the gallon) that a new supply obtained from the chalk has been brought from the district of Wingham, 14 miles from Margate. The chemical and the bacteriological analyses of this water have given very satisfactory results and the yield is more than equal to the demand.

MILK-BORNE SCARLET FEVER.

AN outbreak of scarlet fever which occurred in the Little Woolton sanitary district in Lancashire is described in a recently issued report by Dr. C. Stuart Pethick, the medical officer of health, who inclines to the view that the infection was milk-borne. Little Woolton is a small township which in 1901 contained 218 inhabited houses with a population of 1091 persons. Between November, 1903, and March 29th, 1904, no cases of scarlet fever were notified, but between March 29th and April 16th there occurred 30 cases and of these patients 28 received their milk from the same dairy farm; in some of them the initial throat symptoms were severe and there were two deaths. On April 10th handbills were delivered at each house advising that the milk should be boiled and that no cans should be admitted to the premises. The farmer also ceased to supply milk from his own farm for a period of six days from April 12th. In Dr. Pethick's opinion the dates above mentioned point to the probability (1) that the outbreak was due to some infection of the milk which came into operation about March 25th, and (2) that for 10 or 11 days the milk was receiving a continuous supply of infection. The district then remained free from the disease until June 13th. On April 6th the farm was visited and a careful examination of all the persons residing or employed there was made without eliciting any explanation of the outbreak. The milk, however, was supplied to 46 households in 20 of which the disease appeared. It was taken out in the farmer's cart and either ladled directly into the customers' vessels or into separate little cans which were left at the houses. Mr. Stafford Jackson, M.R.C.V.S., of Liverpool reported that the farmer's herd of ten cows was in a perfectly healthy condition and an examination made by Dr. Albert S. F. Grünbaum of the University of Liverpool showed that there were no micro-organisms in the milk beyond those ordinarily found.

THE PRINCE OF WALES.

WITH reference to the recent operation upon the Prince of Wales we understand that His Royal Highness's progress is entirely satisfactory, an assurance which His Royal Highness's excellent health, his love of outdoor exercise, and his simple habits would lead us to anticipate.

THE PROPOSED UNION OF MEDICAL SOCIETIES IN LONDON.

WE published last week a letter from the President of the Royal College of Physicians giving notice that a meeting would be held on Monday, April 10th, at 5 o'clock, at the Royal College of Physicians to consider the advisability of the union of the medical societies of London in one Royal Society of Medicine. It is certain that the idea has aroused the interest of members of the societies and that the meeting will be well attended. Among the leading men of our profession there are many in favour of the plan of union, some of whom will speak at the meeting. But, after all, it is not they who would most enjoy the advantages of a new Royal Society of Medicine but rather the younger men, who can ill afford the expense of belonging to many societies. There is a certain loss of enthusiasm in the present system because subjects which should be debated in the presence of all interested in them come up for notice now in front of one group of men and now in front of another. This means a loss of strength in the conclusions come to and should be remedied by a scheme of union.

SCHOOL HYGIENE.

WE have but recently discussed some aspects of this important subject in a leading article[1] and we have now before us a report submitted to his health committee by Dr. A. Mearns Fraser, medical officer of health of Portsmouth. Dr. Fraser's report is practically a *précis* with comments by himself of the proceedings of the Conference on School Hygiene recently held at the University of London. He endorses the opinion so strongly upheld at the conference, and one in which we cordially concur, that every education authority should possess an expert medical and sanitary adviser. In his remarks on school furniture Dr. Fraser reminds his readers of what is perfectly obvious—namely, that children are of different sizes and therefore that one pattern of seat will never be quite satisfactory. He recommends a modified "Sheffield system," consisting of one fixed desk of such a length as to give room for six children. The children sit on separate seats with backs, and these seats as well as the desk are screwed to the floor. Dr. Fraser's modification is simply to make the support of the backs curved instead of straight. He maintains that the alternative of separate adjustable seats and desks for each child is too expensive to be adopted. Considering how important it is that all children should be able to sit comfortably upon their seats at such a distance from the desk as may suit them we should have thought that some way might be found of making that portion of the seat on which the child sits adjustable after the fashion of the back seat of a dog-cart without much additional expense. Dr. Fraser's report, however, is certainly well calculated to make the education authority which he addresses take an interest in the duty of providing sanitary methods of education for the 40,000 children with the care of whom it is intrusted.

GERMAN MEDICAL CONGRESS.

THE twenty-second "Congress for Internal Medicine" will be held from the 12th to the 15th of this month at Wiesbaden, under the presidency of Professor Erb of Heidelberg. Professor Ziegler (Jena) will deliver an address on the Present Position of the Doctrine of Heredity in Biology and Dr. Martius (Rostock) will read a paper on the Significance of Heredity and its Rôle in Pathology, especially in regard to Tuberculosis. Amongst the communications to be read at the Congress are the following:—The Treatment of Leukæmia by the Roentgen Rays, by Dr. A. Hoffmann (Düsseldorf); Investigations in regard to the Secretion of Mucus by the Intestines, by Dr. Schütz (Wiesbaden); the Treatment of Cardiac Affections by Electric Baths (Alternating Currents), by Dr. A. Laqueur (Berlin); the Mechanism of the Circulation, by Dr. Homberger (Frankfort); and Some Observations on Experimental Diabetes, by Dr. Lüthje (Tubingen). In connexion with the Congress there will be an exhibition of scientific instruments, apparatus, and preparations of special interest to physicians. Notices of communications are to be sent to Geheimrat Dr. Emil Pfeiffer, 13, Parkstrasse, Wiesbaden.

ACCIDENTS IN MINES AND FACTORIES.

IN another column we publish a statement sent to us by the metropolitan branch of the Association of Certifying Factory Surgeons concerning certain clauses of the Bill now before Parliament to amend the Factory and Workshop Act of 1901. The Bill is down for second reading on April 10th but as the Budget is fixed for that day there is but small chance of its being considered. To put the matter shortly, the Act of 1901 divides accidents into two classes called A and B. Those in Class A are reported to the factory inspector and to the certifying surgeon and are investigated by the latter. Those in Class B are reported to the inspector only and no power apparently exists by which the inspector can report such accidents to the surgeon. The amending Bill, which is the outcome of the report of the Departmental Committee appointed by the Home Office to inquire into the notification of industrial accidents, seeks to overcome this anomalous position by practically eliminating the certifying surgeon. That is to say, accidents under both Classes A and B of the Act of 1901 (in the amending Bill they are divided into A, B, and C) are to be reported to the inspector only. The inspector shall then in such cases as the Secretary of State directs notify the certifying surgeon. The contention of the Association of Certifying Factory Surgeons is that Clause 4, Section (1) of the amending Bill should be amended by adding words to the effect that accidents coming under the heads of A and C should be reported to the certifying surgeon as well as to the inspector In our opinion it is unfair to lay upon the inspector (even when aided by the Secretary of State), who can obviously know nothing of the circumstances, the duty of deciding whether or not to report the accident to the surgeon. The inspector himself can have only the employer's version before him upon which to form an opinion and already the inspector appears to be much overworked. The report of the Departmental Committee, p. 18, states that, "on an average, he is only able to pay one visit a year to each factory." We invite Members of Parliament and others interested in the subject to consider carefully the objections and suggestions made by the Association of Certifying Factory Surgeons and to examine the sections to which we have referred with the following question in their minds. Will the alterations proposed to be made tend to increase or to diminish the inquiry into all accidents in factories by competent and independent investigators? We do not, as the matter stands, see that the amount of information thus obtained will be augmented by the changes proposed.

---

[1] THE LANCET, March 11th, 1905, p. 653.

TODMORDEN'S WATERWORKS.

One of the conditions of modern life is that almost every town in the kingdom is engaged in a struggle for water. For some years Rochdale and Todmorden have been carrying on such a contest but after "a stiff Parliamentary fight" it was decided that Rochdale should take over the Ramsden reservoir and that Todmorden should construct works at Gorpley. The reservoir at the latter place has been constructed to hold 130,000,000 gallons which will give an estimated daily supply of 621,000 gallons exclusive of compensation water. "One feature of the work is the removal of all vegetation from the bottom and sides of the reservoir." As a result of this it is stated that the water, even without filtration, is remarkably free from colour. Notwithstanding this fine sand filters have been constructed of such area that the downward flow at the surface of the sand will only be about four inches per hour when all the water is being used. At this "slow rate of filtration a gelatinous film of mud and microbes forms on the surface and so long as this film is maintained intact the most minute organisms cannot pass it." What is very unusual is that the estimates of cost and also of rainfall were on the safe side. The total cost will probably be just over £90,000. The works were formally opened on March 23rd and the water was turned on by the chairman of the waterworks committee.

THE AERIAL DISSEMINATION OF SMALL-POX.

At a sessional meeting of the Royal Sanitary Institute held at Newcastle-upon-Tyne on March 4th of this year, Dr. Louis C. Parkes being in the chair, Dr. H. E. Armstrong read a short communication on the aerial dissemination of small-pox infection round small-pox hospitals. He drew attention to the issue in November last by Dr. G. S. Buchanan of the report to the Local Government Board on small-pox in Gateshead and Felling in relation to Sheriff Hill Small pox Hospital. Dr. Buchanan there expressed the opinion that the use of this hospital had been responsible, directly or indirectly, for a material portion of the epidemic in Gateshead and Felling and recommended that the hospital should no longer be used for the isolation of small-pox. Dr. Armstrong proceeds to give some interesting details in relation to a sharply defined group of 12 cases of small-pox at St. Peter's, in the east end of Newcastle, notified between June 27th and July 16th in last year. Ten of these cases occurred in one street of tenement dwellings; the remaining two cases were in closely adjoining streets. As careful inquiry failed to trace the origin of any of these 12 cases, attention was drawn to the possibility of infection having been conveyed through the air from Gateshead or Felling. Of the 12 cases of small-pox in question the possible infection period occurred on days when the wind was blowing from the south-east in five cases, from the south-west in one case, and from the south in six cases. In one instance only was the disease likely to have been contracted when the wind was in a northerly direction on days of possible infection. The significance of the foregoing particulars will be understood when it is explained that a south-east wind blows directly from the Felling Small-pox Hospital and a south-by-west wind directly from the Sheriff Hill Hospital across the river to the locality where the above cases of small-pox occurred. The former hospital is a little under a mile and the latter a little under two miles distant from the site of the outbreak of the disease. Dr. Armstrong refers to one possible explanation of the convection of the variolous poison to a great distance which has not yet received the attention which it deserves. House flies are frequently a pest in small-pox wards, settling on the face and other exposed parts of the patient when the eruption is pustular or crusting. With feet and proboscis perhaps laden with the poison they may presently reach the open air and may be carried by the wind to a considerable distance and so convey infection. The attainment of a suitable site for a small-pox hospital often presents the greatest difficulties but from recent experience there is no doubt that it should be as far removed from ordinary houses as is compatible with convenience of working and other practical needs.

In Brisbane for the week ending Feb. 18th there occurred 5 cases of plague but none was fatal. As regards Hong-Kong a telegram from the Governor received at the Colonial Office on March 27th states that for the week ending March 25th there were 1 case of plague and 1 death from the disease. As regards the Cape Colony, the medical officer of health of the Colony states that for the week ending March 11th the condition of the Colony as to plague was as follows. At East London 4 cases of plague were discovered during the week. Plague-infected rodents were found both at Port Elizabeth and at East London and at the latter place was also found 1 plague-infected cat. In other districts there was no plague infection found in man or other animal.

A donation of £4000 from Mr. Alfred Beit and one of £3000 from Messrs. N. M. Rothschild and Sons towards the £100,000 required have been received by the treasurer of Guy's Hospital.

A SANATORIUM ON WHEELS FOR THE TREATMENT OF TUBERCULOSIS.

By Walter H. Haw, B.A., M.R.C.S. Eng.

I should like to bring the following suggestions before the profession with regard to the treatment of phthisis, but before doing so I should preface my remarks with a few observations on the prevailing ideas in connexion with its treatment. The aims of the sanatorium regimen are practically as follows: provision for the plentiful supply of fresh air and sunshine; protection from cold winds, rain, &c.; regulated exercise; regulated rest; proper food and in sufficient quantities; encouragement of appetite; bathing; destruction of bacilli; prevention of dust; food for the mind; amusements; proper clothing; coöperation of the patient in his own treatment; and the whole with a view to increasing body resistance. These aims are carried out at great expense and trouble at sanatoriums and according to published accounts with much benefit to the patients. The advantages claimed are these: (1) constant medical attendance and supervision; (2) absence from disturbing influences; (3) good food and encouragement of appetite; (4) regulated rest and exercise; (5) the improving effect of seeing others improve; (6) the hope of getting well; (7) pure air; and (8) the patient learns how to live.

Although I do not intend to go into any details of the scheme I think that I shall be able to show that most, if not all, of these principles can be carried out in a simple way and in one which personally I have proved of benefit in an illness of my own, not however phthisis. The method is as old as historical South Africa and is simply the adaptation of the bullock wagon to the present-day needs of phthisical patients. My suggestion is, in short, a long journey by bullock wagon to occupy about six months. As my object is merely the suggestion of the plan I shall limit myself to a few details.

Requirements.—A strong bullock wagon which could be fitted up according to the fancy of the traveller, but one with a tent covering half the body of the wagon would be most suitable and it should be rainproof and provided with windows and well-fitting flaps. There should be steps also for mounting. A moveable bedstead and spring mattress for use either in or out of the wagon and all other necessaries of a bedroom could be arranged in the tented part and could be so made as to be easily disinfected. Racks for books, guns, &c., could be fixed around the sides. The flap covering in the front of the tent might have an opening for the head for night sleeping when the weather was not favourable. The luggage might be carried on the front half of the wagon and this might include camera, instruments for entomology, botany, &c., according to the taste of the traveller. A paraffin stove would be essential. Further, a cow in milk could accompany the bullock team and run alongside. As the rate of travel would be only two miles per hour and the outspans would be frequent there would be no fear of overtiring the beast. A fowl coop could also be swung beneath the wagon but should feathered neighbours be objected to they might be dispensed with, for fowls could always be obtained at the farmhouses. If taken the coop should be so constructed as to be easily cleaned and disinfected. A barrel for boiled water should also be provided as well as a bell tent and spittoons for collecting the expectoration if any. The clothing should be carefully chosen for extremes of heat and cold. Lastly, a good cook, a valet for those who could afford one, a driver and leader for the oxen, and, very important, advice from an old transport rider who knows the ropes of veldt travel. In fact, it would not be difficult to get one as driver.

Let us see how far the above principles of treatment can be carried out in what has been called the ship of South Africa.

Fresh air.—The patient would almost be compelled to live in the open air, the only protection, which, however, would be safe and ample, being the half tent on the wagon and the bell tent. As long as the weather was fine the patient would be by preference in the open air. In bad weather the tents would afford efficient protection. In fine weather he could sleep in the open, in less favourable weather he could sleep on the bedstead in the wagon tent, the head being in the open air through the opening in the forward flap of the wagon tent, proper provision being made against sun, wind, and rain for its protection. Details could very simply be arranged. It would be possible, then, for a patient to make a journey in a properly appointed wagon not only in comfort but in comparative luxury and to be breathing fresh and changing air for the whole of the time. The variability of the air I consider to be a matter of great importance and together with the varying nature of the atmospheric temperature it would tend quickly to increase the resistance of the body. As regards sunshine, I need only say that South Africa is the land of sunshine.

Protection from cold winds and rain and in summer from the heat of the sun.—As it has been proved by observers that cold *per se* is not harmful to phthisical patients this question resolves itself into one of clothing. Provision should be made for very cold weather, for it is by no means always warm in South Africa. On windy days a sheltered spot could usually be found for outspanning. Provision should also be made against heat but I may say that the heat in the southern portions of the colony is never unbearable. Rain must be guarded against by attention to the proper details.

Regulated rest.—Rest could be taken either during the time of travelling or during the time of outspanning. The two forms of rest differ, that during travelling being combined with more or less massage according to the nature of the road and [illegible]

Regulated [illegible] e taken either during travelling or outspan hours. As the bullocks travel at the rate of about two miles an hour the rate could be varied; it would be quite easy for a weakly patient to get his exercise at any time of the day most suitable.

Diet.—Diet would be the chief difficulty but it might be overcome with the help of a good cook and a paraffin stove. I am informed by a good housewife that there should be no difficulty, given a good cook and stove, in making any delicacies required within limits, which limits are, I think, salutary. There need be no trouble in getting milk, vegetables, butter, butcher's meat, fowls, or eggs. Personally, I know of no better stimulant to the appetite than a holiday-trip in a bullock wagon. The water for drinking purposes would require to be boiled.

Dust.—In this regard there need be little fear that the dust encountered would be tubercle-laden except in those towns which had become so-called health resorts for consumptives, and such towns could be avoided, so that the only precautions in this respect would be to wear a nasal filter on dusty roads.

Destruction of bacilli.—The infection of the wagon from the patient would have to be guarded against by means of close attention to the expectoration, which should be carefully collected in spittoons and burnt at the next outspan. The whole wagon could be cleaned and thoroughly disinfected with its contents once a week. In fact, every precaution would have to be taken that no expectoration or discharge of any kind was left on any article in the wagon.

Bathing.—A light bath could be taken as part of the luggage but I think that most of the bathing should, after a time, be indulged in in the streams in those districts which are free from bilharzia.

Mental food.—A small library could be arranged in the wagon and there are good libraries in most of the towns. Splendid opportunities are afforded for botany, geology, ornithology, and entomology.

Amusements.—Shooting (birds and antelope), tennis, croquet, golf, boating, &c., could all be obtained at the proper times and places, if sought after.

Society.—Those fond of social functions could make a halt near a town. Acquaintances are soon made in South Africa. But social functions should be avoided during the treatment.

I have not gone into the matter of the cost of this plan of treatment of phthisis but I should roughly estimate the hire of a turn-out to be as follows: wagon, 2*s.* 6*d.* per day; bullocks, 6*d.* per head per day; driver, 5*s.* per day; and leader, 2*s.* 6*d.* per day. This is what I have actually paid for a wagon during a holiday. To wealthy people the best plan would be to purchase a turn-out and to sell it at the conclusion of the tour.

I hope I have said enough to point out the advantages of this method of treatment and I will now conclude with a word or two upon the disadvantages. To one born and bred in South Africa it would be somewhat hard to see the disadvantages, for such a mode of travelling means health pure and simple, but to those brought up in luxury, and especially to those who are phthisical and whose delicacy may seem a contra-indication, it might be thought that the partial "roughing it" would be a grave disadvantage. But this is not so. As in sanatoriums, the cases would have to be properly selected. It would, for instance, be madness to send a patient with advanced lung disease, high fever, and prostration on such a journey (it would be madness in theory but I believe that it has still to be proved so), but in suitable cases of incipient and quiescent lesions I do not think a more effective method of increasing body resistance could well be found, involving as it does fresh air, rest, exercise, wholesome food, mental and bodily change, and, I was almost going to say (so great is my belief in its efficacy from personal experience), the certain improvement in health. Of course, I could enumerate a long list of what would be looked on as disadvantages, but in the end these would be found to be really advantageous to the proper treatment of phthisis, which is the gradual education of the body to increased resistance to the tubercle bacillus. I wish that an abler pen than mine could have advocated this method, but failing this I send the foregoing in the hope that it may revive hope in the breast of some poor victim to the disease, and I think I may tell him with confidence that if his case is a suitable one and he has the means to carry out the treatment he will benefit enormously in health and vigour.

Knysna, Cape Colony.

PRESENTATION.—At Hong-Kong on Feb. 24th Dr. J. M. Atkinson and Mr. J. Bell, the superintendent of the Government Civil Hospital, were presented with a gold cigarette case each. The presentation was made by His Excellency Sir Matthew Nathan, on behalf of the Tsar, who had sent the cigarette cases out to the two recipients for their attention to, and care of, the officers and sailors of the Russian cruiser *Varyag*, while they were in Hong-Kong. The cases bear the Imperial crest set in diamonds.

THE THOMPSON YATES AND JOHNSTON LABORATORIES REPORT.[1]

THIS interesting publication includes the Reports of the Trypanosomiasis Expedition to the Congo, 1903–1904 (Memoir XIII.), of the Liverpool School of Tropical Medicine and Medical Parasitology, by Dr. J. Everett Dutton, Dr. John L. Todd, and Dr. Cuthbert Christy; with a Comparison of the Trypanosomes of Uganda and the Congo Free State by Dr. H. Wolferstan Thomas and Dr. Stanley F. Linton, as well as a Note on Tsetse Flies, by Mr. E. E. Austen. The contents of the volume are largely devoted to subjects appertaining to tropical medicine and to trypanosomiasis and sleeping sickness especially. Some of the papers have already appeared in medical journals but it is convenient to have the important observations made by the members of the various expeditions sent out by the Liverpool School of Tropical Medicine brought together in one volume.

The first articles—No. I., Human Trypanosomiasis on the Congo, No. II., Human Trypanosomiasis and its Relation to Congo Sleeping Sickness, and No. III., the Congo Floor Maggot—have been published in various journals and formed the subjects of papers at the British Medical Association meeting at Oxford in July, 1904. Dr. Dutton, Dr. Todd, and Dr. Christy were engaged in elucidating and investigating the various points of trypanosomiasis as it affected human beings and their careful work is well known.

In article No. IV. Dr. Christy discusses the cerebro-spinal fluid in sleeping sickness (trypanosomiasis) and analyses the results of 104 lumbar punctures. The conclusions at which he arrived were: (*a*) That in many cases of trypanosomiasis the trypanosomes never find their way into the cerebro-spinal fluid and in those in which they do it is during a late stage of the disease; (*b*) that the parasites come and go in the fluid; (*c*) that they may appear in the blood without being present in the fluid and *vice versâ*; and (*d*) that there is no relation between the commencement of fever and other symptoms and the entrance of the parasites into the cerebro-spinal fluid.

Article No. V., by Dr. H. Wolferstan Thomas and Dr. S. F. Linton, is devoted to a Comparison of the Animal Reactions of the Trypanosomes of Uganda and Congo Free State Sleeping Sickness with those of Trypanosoma Gambiense. This article, which was published in THE LANCET of May 14th, 1904, gives a detailed account of the investigations which succeeded in showing that the trypanosomes found in (*a*) the cerebro-spinal fluid of cases of Uganda sleeping sickness, (*b*) the cerebro-spinal fluid of cases of Congo Free State sleeping sickness, (*c*) the blood of cases of Uganda trypanosome fever, and (*d*) the blood of cases of Congo Free State fever are all identical in animal reactions and morphology with the trypanosoma Gambiense. They further determined: (1) that there seems to be no acquired immunity against infection; (2) that there is no transmission of immunity to offspring; and (3) that an animal which seems to have recovered may months later show parasites once more, apparently as the result of lowered vitality.

Article No. VI., by Dr. Dutton, Dr. Todd, and Dr. Christy, gives a detailed account of Two Cases of Trypanosomiasis in Europeans. One case was that of a woman, aged 35 years, who gave the history of being severely bitten by "river flies" in August, 1901. This was succeeded in six days by a severe fever which lasted for 25 days. This attack was succeeded by a weekly fever which continued for three months. Each febrile attack lasted about five days. From January to April, 1902, the temperature ranged between 99° and 100° F. and was never normal. On arriving in England in April, 1902, the temperature gradually fell to normal and twice between the date of arrival and August, 1903, when she returned to the Congo, did febrile attacks occur. Red patches of about the size of a half-crown and lasting for three or four days appeared on the legs whilst in England. She had stiff joints and an "inflamed throat" and the eyes were "inflamed." On returning to the Congo febrile attacks again developed on Oct. 10th and Nov. 9th and 14th, 1903, but there was no more fever until March, 1904. On June 2nd, 1904, the last note on this patient was, "For last few days patient has complained of lack of appetite and loss of energy; the swellings on face and hands persist; a papular eruption has appeared on the chest." The other case recorded is that of a captain of a steamer on the Congo, aged 28 years. The inference gathered from a study of this case is stated as follows: "It therefore seems probable that the incubation period between the time of the infection with trypanosoma Gambiense and the appearance of the symptoms associated with human trypanosomiasis may be so short as four weeks."

Article No. VII., by Mr. Ernest E. Austen, is entitled "Supplementary Notes on the Tsetse Flies (Genus Glossina, Wiedemann)." Since Mr. Austen's publication of a monograph of the tsetse flies in 1903, when seven species of tsetse flies were recognised and described, an eighth species, glossina Decorsei, has been described by Dr. Emile Brumpt from specimens recently obtained by Dr. Decorse on the River Shari and the shores of Lake Chad. This parasite has already been described[2] together with a detailed account of the several species of the tsetse flies.

In articles Nos. VIII., IX., X., and XI., Dr. J. W. W. Stephens contributes four articles to the January series of 1905: (*a*) A New Hæmogregarine in an African Toad; (*b*) Two Cases of Intestinal Myiasis; (*c*) a Note on the Pathology of Tropical "Swellings"; and (*d*) Non-flagellate Typhoid Bacilli. The hæmogregarine was obtained from one of a batch of toads received from Sierra Leone in October, 1903. Although the description of the cyst and its polar masses of this recently observed parasite differs in some respects from previously described hæmogregarines in amphibians and reptiles, Dr. Stephens, owing to the similarities which it bears to others, is inclined to defer proposing a name for the gregarine which he describes. The larvæ of the flies met with in the intestine of two children in Liverpool were found by Dr. Stephens to belong to two species—viz., those of the musca corvina and the homalomyia canicularis. The patient, the subject of tropical swellings, went to Liverpool from Degama, Southern Nigeria. He was the subject of peculiar swellings in the hands, the arms, the face, and the feet which were of a fugitive character and seldom occurred in more than one place at a time. The leucocytic count (600 counted) gave large mononuclears, 1; small mononuclears, 23; polynuclears, 26; and eosinophiles, 50. No filariæ were found. The condition appears to differ from that present in "Calabar swelling."

Article No. XII., by Mr. A. E. Shipley, F.R.S., gives an account of a Human Parasite from Africa, the Cladorchis Watsoni (Conyngham). The patient came from German West Africa and was one of a gang of freed slaves. He had constant diarrhœa; the stools passed contained numerous reddish-yellow, translucent, gelatinous, oval bodies. After death the oval bodies were found in the contents of the upper part of the small intestine and proved to consist of a trematode belonging to the family paramphistomidæ (Fischoeder) and to the sub-family cladorchinæ. Man would appear to be but an occasional host of the parasite, the normal host being in all probability some herbivorous animal.

Article No. XIII., by Dr. Dutton, deals with the filaria of the African swift—Cypelus affinis. In the lice infecting the feathers of this bird the embryo of filaria cypseli was found. In the bird parent filariæ were found and embryos were met with in the lymph passages. The louse serves as an intermediate host and the bird by picking off the lice from amongst its feathers in all probability reinfects itself.

Article No. XIV. by Mr. Benjamin Moore and Mr. Herbert E. Roaf, is an elaborate account of an Experimental Study of the Physical Chemistry of Anæsthesia in Relationship to its Causation. Mr. Moore and Mr. Roaf conclude that chloroform forms an unstable chemical compound or physical aggregation with the proteids experimented with and that it is carried in the blood in such a state of combination. The oxygen-carrying power of hæmoglobin is not interfered with in presence of chloroform.

Article No. XV. by Mr. E. S. Edie, consists of a description of experiments on the Action of Chloroform on the Proteids of Serum and upon Solution of Hæmoglobin.

Article No. XVI. is devoted to an account of a Simple Method for the Preparation and Determination of Lecithin, by Mr. Roaf and Mr. Edie.

MEDICINE AND THE LAW.

The Determination of Age in the Living.

THERE are numerous practical occasions when the age, usually of a minor, is of forensic interest. The fact may be required for registration purposes (marriage, census returns, or death), for exemption from attendance at school, and under the Employment of Children Act, 1893, for indictments under the Criminal Law Amendment Act, 1885, and the Prevention of Cruelty to Children Act, 1904, for superannuation, and notably in the application of the legal presumptions that a child of less than seven years is incapable of committing an indictable offence and can only be punished if under 14 years of age on proof of actual malice. English statutes usually impose the onus of proof upon the defendant; at the common law in cases of dispute infancy is presumed. Certificates of birth, baptismal registers, and, as with a case in 1806, the receipted entry in an accoucheur's day-book have all been produced and admitted as valid evidence. There are, however, cases where such documentary evidence is not forthcoming; the age of these persons must be presumed; they include persons born abroad, orphans, and homeless wanderers. It is a well-known fact that skilful clinicians may cultivate the instinct of correctly surmising the age of their patients to a remarkable degree of accuracy. The precision is usually greater when the facial inspection occurs with the patient in bed and unadorned by deceptive peculiarities in the mode of dressing the hair or arranging the clothes. Recent Acts have adopted the principle of facial diagnosis: "Where a child is ...... alleged ...... to be under any specified age and the child appears to the court to be under that age, such child shall for the purposes of this Act be deemed to be under that age unless the contrary is proved." Bracton in 1219 relates how the evidence of the mother and other relatives was admitted and also how a jury of 12 "legales homines" was empannelled for the determination of the age of a would-be minor. To-day an affidavit or a statutory declaration before a magistrate may be necessary as a warranty and hence arises the nice legal point as to how far, apart from documentary and hearsay evidence, a person can be said to know his own age—a point which was raised recently in the State of Iowa Courts. To what extent can the physiologist afford real evidence by the "ocular demonstration" of which a scientifically accurate result may be obtained where a living person's exact age is in dispute? The state of dentition may assist and, perhaps, the presence of secondary sexual characteristics may be of service. Stow, the chronicler, tells us that it was the rude application of this latter test by a collector of the poll-tax which culminated the discontent and led to the peasants' insurrection of 1381.

Embalming in its Medico-legal Relations.

In the United States of America the temporary preservation of the dead body from putrefaction is becoming increasingly popular and in England there are nearly 50 towns where embalmers skilled in the art are to be found. Interest is therefore raised by the discussion which the New York Medico-Legal Society has just concluded on a report presented by a select committee of its members appointed to consider a case (The People *v.* Patrick) where a prisoner was sentenced to death for murder (homicide in the first degree) by the New York Criminal Court in 1902. The following were the main facts of the case. A man, aged 84 years, died, the certificate of his regular medical adviser affirming several causes of death which in sum amounted to the diseases to which the aged are heirs. Two hours after death, before rigor mortis had set in, an embalmer injected a solution of formalin into the right brachial artery of the deceased, no blood being abstracted from the body. 41 hours later a necropsy was performed prior to cremation. Among other conditions it was recorded that the lungs were "congested and œdematous"; the lungs were cremated with the corpse. Some time afterwards the valet of the deceased confessed that while the old gentleman was lying on his back asleep he placed a sponge soaked with chloroform and covered by a towel over his aged master's mouth and then left him for half an hour. On his return death, he said, had supervened. He then burned the sponge and the towel which, he stated, blazed as if they were "soaked with oil." Collateral evidence gave no hint that there were any traces, to sight or to smell, of chloroform having been recently used in the room or on the person of the dead man. The valet's confession, together with the report of the condition of the lungs at the time of the necropsy, were held to substantiate the crime and accordingly he was sentenced capitally. It was decided by the society to investigate the purely medico-legal facts in issue, quite apart from the legal questions of motive and intent; hence the nomination of a committee of experts and its report referred to above. The conclusions may be summarised thus: the naked-eye appearances produced in the lungs by the method of embalming employed in this case might be mistaken for ante-mortem congestion and even for asphyxia by chloroform, microscopical examination would be necessary in order to differentiate the alternative conditions; the jury was hardly warranted in giving its verdict on the partial evidence adduced, for there was nothing in the appearance of the lungs *per se* conclusive or even indicative of the cause of death, indeed, the original death certificate was warranted by the facts presented; the embalming process may complicate the true post-mortem appearances of a corpse. Where it is desired by friends to have a dead body embalmed it may be taken as a good rule not to commence the operation until the formal certificate of death has been received.

Neglect to Call a Medical Witness.

It is not easy to understand the attitude taken up by Mr. E. H. Hall, [illegible] holding an inquest upon the bo[illegible]own in the borough who beyond [illegible] when depressed by business wo[illegible] under the explicit direction of the coroner to that effect was that the deceased died from a wound inflicted on himself but that there was not sufficient evidence as to the state of his mind at the time. This would give the impression to anyone hearing of it that the deceased had committed *felo de se* or that at all events no one had noticed any peculiarity of demeanour or otherwise before his death who could speak with any authority upon the matter. As a matter of fact, however, Dr. Arthur Drury, who had been the medical attendant of the deceased for 16 years, had on the evening before his death had a prolonged interview with him and this gentleman within a few hours of the death informed the coroner that he had evidence to give of importance directly bearing upon that subject which, to the survivors at all events, is of the greatest importance upon such occasions. Many coroner's juries return verdicts of "Suicide during temporary insanity" with but scanty evidence to justify them, but the rejection of evidence tendered by a medical man which might be conclusive upon the point is unusual and undesirable.

A Death due to Christian Science.

A letter recently published in the *Westminster Gazette*, and probably in other newspapers, gave particulars of a very sad case of wholly unnecessary death due to the absurd craze or imposture known as Christian Science, which in some respects differs from other reported instances of the same kind in that, to the majority of her relatives, at all events, the deceased was not known as a "Christian Scientist." The writer does not disclose either his own name or that of those directly implicated but there seems to be no reason to doubt the truth of the facts narrated and there are obvious causes for anonymity being preserved. The deceased, a lady and an old friend of the writer, went to stay with her son, a "Christian Scientist," residing in London, from whose peculiar views she had until then been believed to differ. A fortnight later her relatives were informed by the son that she had been taken ill and had "passed on," apparently a "Christian Scientist" euphemism for death. Inquiry showed that she had had a severe attack of influenza and under "Christian Science" treatment had developed acute bronchitis. A medical man had been called in when she was dying; he had not been told anything about "Christian Science" being involved, and when a few hours later the lady died he had given his certificate as to the cause of death which was not in any way obscure. This apparently was the only reason for his intervention being sought at the eleventh hour. The relatives of the lady, acting under natural indignation against the travesty of religion named and having no legal redress against the son or any other of its practitioners, desire to make the case public for the warning of others. It presumably was an occasion upon which, had the medical certificate been withheld, an inquest would have followed, at which some inquiry would have been possible as to the opportunity which the unfortunate lady had for obtaining medical aid and how far she herself acquiesced in the absence of it. Whether at this late period the matter should be reopened is another matter; presumably there is no evidence to justify any action being taken. Had the deceased been a child the matter would, of course, have assumed a different complexion.

THE MEDICAL INSCRIPTIONS OF THE COLUMBARIUM LIVIAE.

THE immense collection of inscriptions dating from the time of the Roman empire that has been gathered together in the great "Corpus Inscriptionum Latinarum" necessarily contains many texts relating to medical men in various parts of Italy and even in the distant provinces of the Roman empire. The volumes, the contents of which are confined to the publication of inscriptions discovered in Rome or its neighbourhood, present more than the average proportion of these medical memorials because they include the series of many physicians and surgeons whose remains were placed in the "columbarium" of Livia, wife of Augustus, which was excavated, near the Appian Way, in A.D. 1726. The texts from this special site, as will appear, throw a vivid light upon the organisation of the various classes of professors of the healing art as permitted to exercise their vocation in the time of Augustus under a system really determined by Cæsar's decree regulating the cultivation of all arts and sciences. For a complete account of the information afforded as to medical matters by Latin inscriptions it will be necessary to quote and to comment upon many texts relating not to practitioners but to the deity Æsculapius, and his hierarchy, because it was within his temple that the medical profession first dispensed the benefits of its knowledge to their fellow men. But the present notes will be confined to a summary of various inscriptions relating to medical men in the time of the Cæsars.

Two texts from the Columbarium Liviae may be quoted as indicating different grades of medical officers at the court. The first reads: M . LIVIVS . LIVIAE . L . ORESTES . SVPRA . MED. This shows that Orestes, perhaps of Egyptian origin, had attained to the position of supra medicus, "superpositus medicorum," an office evidently of superintendent of all those under his command engaged in the treatment of disease. It may be also that he had the rights of inspectorship and supervision over persons indirectly connected with medicine, such as the adiutores valetudinarii and unguentarii and others. The second text preserves the title of a "decurio medicorum"; it reads: M . LIVIVS . BOETHVS DEC . MEDICO.

The following inscription derived from the same place gives the name of a surgeon; it is No. 3986 in the "Corpus," AVG . HILARVS . MEDIC . CHIRVRG. Another which succeeds it would seem to indicate the commencement of specialism, though merely reading MEDIC . OCVLARIVS, the name having unfortunately been broken away. Aural specialists were known to have flourished and classic authors speak of them. A text in the Naples Museum confirms this, it being that of "T. Aelius . Aminias Medicus Auricularius." Another of these known from literature was named Celadianus who practised under Augustus. His memorial epitaph was recovered near the Via Latina and shows that he died whilst quite young. It reads, "Thyrius Ti ...... Cæsaris, Aug ...... Ser ...... Celadianus Medicus Ocularius. Pius parentium suorum. Vixit Annos XXX." The next inscription is that of a freedman, not of Livia but of Drusus, and is given here because it is perfectly legible throughout. It may be found in the sixth volume, Part II. of the "Corpus" under the head of "Monumentum libertorum Drusi."

CHRETE . CONSERVEE
ET . CONIVGI . CELADVS . ANTON
DRVSI . MED . CHIRVRG
B(ene) MERENTI . FECIT
VIXIT . ANNOS XVII.

To be specially appointed physician to the Court was just as much an honour then as now and therefore a high office worthy of record in the sepulchre. Therefore a text discovered in the Via Latina reads: "D. M. RVPILIO . CALPVRNIANO . MEDICO . DOMVS . AVGVSTAE," &c. Sometimes these lapidary memorials relate to personages already familiar to us from classic authors or to members of their family. For instance, Pliny, writing of the famous medical men of his time, mentions five names, saying: "Multos praeterea medicos celeberrimosque ex iis Cassios, Calpitanos, Aruntios, Albutios, Rubrios." The succeeding inscription of the time of Domitian refers to a member of the Aruntii family It was found in the Via Nomentana and is No. 8895 of the "Corpus":—

L . ARRVNTIO . SEMPRONANO
ASCLEPIADI
INP . DOMITIANI . MEDICO
T(estimentum) F(ieri) I(ussit).[1]

For signal service to a member of the Imperial family the attendant might be awarded a decoration. Thus the physician of Faustina obtained insignia ATMETO . MEDICO . ET . PARTENOPAEVS . FAVSTINAE . AVG . SERVI . OB . ORNAMENTIS . AMICO . BENE . MERENTI . FECERVNT. Other names given in inscriptions of the early Cæsars are Claudius Athenodorus, doubtless a Greek, Cyrus, perhaps a Persian, Eros, and Titus Flavius who would, however, date from the period of the Flavian Emperors. A personage named Sterope is another instance of a decurion of medicine.

The next inscription is given because it informs us of the existence of a medical library which there is reason to believe was founded by Augustus, or it may be that he was specially custodian of the medical works in the great library.

AVG . L . HYMENAEVS . MEDICVS . A . BYBLIOTHECIS .
ET . DOMITIA . PANNICHIS . SIBI . ET . SVIS
POSTERISQVE . EORVM.

There was a College of the Archiatri whom we shall presently find mentioned in these lapidary texts and it is apparent that there were medical colleges in all the greater cities as there was one upon the Esquiline Hill at Rome. A text at Beneventum refers to property of the medical college there "in perpetuum ad collegium medicorum pertinet." A college would require a secretary, and from Naples we have the epitaph of such a one. "D. T. Aurelius . M. Telesphorus, Scriba Medicorum." The scribe, or clerk, probably was a copyist of medical works belonging to the college. A cippus of a medical man, Curtianus, at Praeneste, has beside its inscription graven upon it a representation of certain surgical instruments and of books. The Archiatri were a superior order of physicians organised by Nero and were of two orders, the "Archiatri palatini" or court physicians and the "Archiatri populares." Antoninus Pius ordained that a committee of these should be formed in all the great cities, by election by the citizens, but it is thought that before they were eligible for such an election they had to pass an examination conducted by the chief college of the Archiatri. We have at least four inscriptions of Archiatri from Rome, one named Timotheus, another Aratus, whilst in the other two the names are obliterated.

We have seen that persons of provincial parentage, certainly Greeks, practised in Rome and there is a text of one "Rapetiga Medicus civis Hispanus" who died under Augustus. Another inscription reads "Egypto Medico Tertia filio carissimo posuit." An oculist P. L. Philogenes was also a Greek. An inscription of a medical man, Demetrius Trallianus, from the province of Naples, is written in Greek, and may be found in the "Inscriptiones Regni Neapolitani" of Mommsen. There were ladies who adopted the healing art as their profession. From the Quirinal comes a text of "Minucia Medica." In the Vatican Museum is one of "Julia Medica," another honours "Terentia Niceni Terentiae Primae Medica." Veterinary surgeons are also represented. No. 9610 in the Corpus is of one APOLLODORVS ...... MEDICVS . EQVARIVS ......; another reads SECVNDINVS . MVLOMEDICVS., and there are more of these. Inscriptions of surgeons attached to the legions naturally are discovered nearer the frontiers. One found in Rome is of a naval surgeon, T. Flavius Euprepetius, who was attached to what might be termed the "home fleet," stationed at Misenum, the marine station of which was just north of Naples. As physicians of the fair sex have been referred to the record of a midwife deserves mention. Her name is an appropriate one: HYGIA . MARCELLAE . L . OBSTETRIX.

---

[1] No. 8897 of the "Corpus" refers to one of the Cassii; and Stertinus Xenophon, the celebrated physician, is mentioned in 8905, a monument in the Vatican Museum.

Looking Back.

FROM

THE LANCET, *SATURDAY*, April 7, 1827.

HOSPITAL REPORTS.

HOSPITAL OF SURGERY,

Panton Square, St. James's.

AMPUTATION OF THE LOWER JAW.

A FEMALE, æt 16, had an ovoid tumour about the size of a turkey's egg, situated upon the right side of the lower jaw, its base extending from the angle of that bone, to within a few lines of its symphysis. The skin covering it was of its natural colour, and moveable on the surface of the tumo [illegible] he touch, and a [illegible] to admit of an [illegible] outh, the tumo [illegible] r to the second incisor tooth of the same side, and the internal lamina of the bone was pushed outwards by the swelling.

She states that the disease first began about three years ago in the form of a gumboil, some weeks after having received a severe bruise on the site of the present tumour; after this, the jaw was observed to swell, and very gradually to increase in size, attended, at intervals, with acute pain until May last, when it had acquired almost its present bulk. An attempt was then made to remove the tumour, it being thought practicable to detach it from the bone. However, on cutting down upon it, the disease was discovered to penetrate into the substance of the bone itself, and a portion only of the tumour was accordingly removed. Soon after this operation, the tumour began again to grow, and increased in size, even more rapidly than before.

As the tumour now involved the whole shaft of the bone, and as it was considered probable that the disease would soon extend so far into the mouth as materially to interfere with deglutition, and sooner or later destroy life, the girl was advised to submit to the complete excision of the affected portion of the jaw-bone; this she assented to, and, accordingly, the operation was performed on the 25th ult.

Note of the Operation, by Mr. Wardrop.

"The operation consisted in,

1st, Making an incision along the cervical edge of the tumour, which commenced at the angle of the jaw, and extended to a little beyond the chin.

2dly, An incision was made at right angles with the first, commencing a little anteriorly to the insertion of the masseter muscle, and extending up the cheek near to the molar bone.

3dly, An incision was next made, dividing the under lip and soft parts of the chin, at right angles, with the first incision.

The two flaps thus formed were dissected back, laying open the cavity of the mouth, and completely exposing the whole of the upper part of the tumour. The edge of the masseter muscle, which lay in immediate contact with the edge of the tumour, was carefully dissected back, sufficiently to expose the bone for the application of the saw. The section of the bone was made immediately behind the last of the large grinders, in an oblique direction, from without inwards. In consequence of the thickness of the soft parts covering the bone, the prominence of the tumour, and the closeness of the upper and under jaw at that part limiting the action of the saw, this was rendered by far the most difficult step of the operation, and it was the most hazardous from the contiguity of so many important organs. The next step of the operation, consisted in sawing through the bone between the two central incisor teeth, which was easily accomplished. The portion of the jaw to which the tumour was attached being now liberated it was easily turned outwards, so that it admitted of being readily dissected from the soft parts within the mouth, with which it was connected. Great care was taken, in this part of the dissection, to divide the soft parts close to the bone.

During the operation it was computed that the patient lost not less than two pounds of blood, the vessels which were divided having bled very freely. Several branches of the angular artery were secured with ligatures, as well as the coronary artery of the lip, during the operation, and only two vessels were tied after the removal of the tumour; the dental artery did not bleed; the lingual artery was exposed, but not wounded.

The edges of the wound were readily brought together, one silver pin being put into the lip at its red edge, and the rest was kept in contact by stitches of the interrupted suture, and a few pieces of adhesive plaster. No bandages or dossils of lint were used, and the parts assumed quite a natural look, when compared to their hideous appearance during the performance of the operation. She endured the operation with the greatest fortitude; and notwithstanding the large quantity of blood lost by so feeble a person, and the great state of exhaustion to which she was reduced, she was not allowed to get wine, or any other cordial, fearing the danger of inflammation supervening, which might have prevented the wounds of the integuments being healed by adhesion."[1]

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8860 births and 4711 deaths were registered during the week ending April 1st. The annual rate of mortality, which had been 17·2, 15·8, and 15·9 per 1000 in the three preceding weeks, declined again last week to 15·7 per 1000. In London the death-rate was 15·1 per 1000, while it averaged 16·0 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 6·8 in Handsworth (Staffs.), 7·4 in Hornsey, 8·0 in East Ham, 9·8 in Bury, 10·5 in Leyton, 10·7 in Grimsby, and 10·9 in Burton-on-Trent; the highest rates were 23·3 in Middlesbrough, 24·3 in Coventry and in Tynemouth, 24·6 in Sunderland, 24·7 in Wigan, 25·8 in Hanley, and 27·5 in Merthyr Tydfil. The 4711 deaths in these towns last week included 483 which were referred to the principal infectious diseases, against 471, 430, and 494 in the three preceding weeks; of these 483 deaths, 214 resulted from measles, 106 from whooping-cough, 51 from diphtheria, 46 from diarrhœa, 33 from scarlet fever, 31 from "fever" (principally enteric), and two from small-pox. No death from any of these diseases was registered last week in Bournemouth, Great Yarmouth, Wallasey, Huddersfield, Rotherham, or York; while they caused the highest death-rates in Southampton, Reading, Hanley, Wigan, Bolton, Middlesbrough, Stockton-on-Tees, and Merthyr Tydfil. The greatest proportional mortality from measles occurred in Portsmouth, Southampton, Reading, West Bromwich, Wigan, Middlesbrough, Stockton-on-Tees, and Merthyr Tydfil; from scarlet fever in Northampton and in Oldham; from diphtheria in Stockport and in Middlesbrough; from whooping-cough in Tottenham, Hanley, Stockport, Preston, and Middlesbrough; and from diarrhœa in Oldham. The mortality from "fever" showed no marked excess in any of the large towns. One fatal case of small-pox was registered in Burnley and one in Hull, but none in any other of the 76 large towns. The number of small-pox patients in the Metropolitan Asylums Hospitals, which had been 16, 23, and 20 at the end of the three preceding weeks, was again 20 at the end of last week; two new cases were admitted during the week, against three, nine, and three in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital on Saturday last, April 1st, was 2032, against 2036, 2042, and 2034 on the three preceding Saturdays; 254 new cases were admitted during the week, against 303, 262, and 274 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respira-

---

strik:

tory system, which had been 304 in each of the two preceding weeks, declined again last week to 273, and were 97 below the number in the corresponding period of last year. The causes of 58, or 1·2 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Nottingham, Salford, Leeds, Hull, Newcastle-on-Tyne, and in 42 other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Smethwick, Aston Manor, Liverpool, St. Helens, Warrington, Preston, Sheffield, Sunderland, and South Shields.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 18·6, 18·2, and 18·3 per 1000 in the three preceding weeks, declined again to 16·9 per 1000 during the week ending April 1st, but was 1·2 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 10·7 in Perth and 16·5 in Paisley, to 17·9 in Leith and 18·6 in Greenock. The 568 deaths in these towns included 20 from whooping-cough, eight from diarrhœa, five from measles, five from diphtheria, four from "fever," and one from scarlet fever. In all, 43 deaths resulted from these principal infectious diseases last week, against 58, 52, and 59 in the three preceding weeks. These 43 deaths were equal to an annual rate of 1·3 per 1000, which was 0·3 per 1000 below the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping-cough, which had been 31, 17, and 33 in the three preceding weeks, declined again last week to 20, of which 14 were registered in Glasgow, two in Edinburgh, and two in Aberdeen. The deaths from diarrhœa, which had been 17, 13, and eight in the three preceding weeks, were again eight last week and included five in Glasgow and two in Aberdeen. The fatal cases of measles, which had been six, ten, and six in the three preceding weeks, further declined last week to five, all of which were registered in Glasgow. The deaths from diphtheria, which had been two, eight, and ten in the three preceding weeks, declined again to five last week, and included three in Glasgow. The fatal cases of "fever," which had been three and one in the two preceding weeks, rose again last week to four, of which two occurred in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 153, 140, and 133 in the three preceding weeks, further declined last week to 105 and were 52 below the number in the preceding week. The causes of 19, or more than 3 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 25·2, 23·8, and 22·4 per 1000 in the three preceding weeks, rose again to 24·9 per 1000 during the week ending April 1st. During the past 13 weeks the death-rate has averaged 24·6 per 1000, the rates during the same period being 16·8 in London and 17·8 in Edinburgh. The 181 deaths of persons belonging to Dublin registered during the week under notice were 18 in excess of the number in the preceding week, and included eight which were referred to the principal infectious diseases, against two, eight, and seven in the three preceding weeks; of these, four resulted from measles, two from diarrhœa, one from scarlet fever, and one from diphtheria, but none from small-pox, whooping-cough, or "fever." These eight deaths were equal to an annual rate of 1·1 per 1000, the death-rates last week from the principal infectious diseases being 1·1 in London and 0·5 in Edinburgh. The four fatal cases of measles corresponded with the number in each of the two preceding weeks. The 181 deaths in Dublin last week included 26 of children under one year of age and 47 of persons aged 60 years and upwards; the deaths of infants showed a slight excess, while those of elderly persons were fewer than those in the preceding week. Three inquest cases and two deaths from violence were registered; and 57, or nearly one-third, of the deaths occurred in public institutions. The causes of 11, or more than 6 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

IN accordance with the provisions of Her late Majesty's Order in Council of April 1st, 1881, Fleet-Surgeon Horace Elliott has been placed on the Retired List at his own request (dated April 1st, 1905).

The following appointments are notified:—Fleet Surgeons: J. W. O. Underhill to the *President*, for three months' course at West London Hospital; J. Chambers to the *Duncan;* and J. Andrews to the *Blenheim* on commissioning.

ROYAL ARMY MEDICAL CORPS.

Major E. M. Morphew is appointed to the Eastern Command for duty at Colchester; Captain A. M. MacLaughlin is temporarily posted to the Military Hospital, Belfast; and Major F. W. Begbie, from Ceylon, is appointed to the London District. Captain H. W. Vaughan-Williams retires on a gratuity (dated April 5th, 1905).

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain C. R. Lawrie to be Surgeon-Major (dated March 25th, 1905).

VOLUNTEER CORPS.

Submarine Miners: The Mersey Division: John Owen to be Surgeon-Lieutenant (dated April 5th, 1905).

Rifle: 7th Volunteer Battalion the Royal Scots (Lothian Regiment): Surgeon-Lieutenant-Colonel J. L. Crombie resigns his commission and is granted the honorary rank of Surgeon-Colonel, with permission to wear the prescribed uniform (dated April 5th, 1905).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

Sherwood Foresters Bearer Company: Captain R. H. Luce is granted the honorary rank of Major (dated April 5th, 1905).

VOLUNTEER OFFICERS' DECORATION.

The following have received the above decoration:—*Rifle:* 20th Middlesex (Artists') Volunteer Rifle Corps: Surgeon-Major and Honorary Surgeon-Lieutenant-Colonel (Honorary Captain in the Army) Richard Reginald Sleman. *Southern Command: Artillery:* 1st Gloucester Royal Garrison Artillery (Volunteers): Surgeon-Lieutenant-Colonel David Samuel Davies, retired. *Welsh and Midland Command: Rifle:* Sherwood Foresters Bearer Company Royal Army Medical Corps (Volunteers): Captain Richard Harman Luce.

THE ARMY ESTIMATES.

The inconclusive debate on the Army Estimates still continues in the House of Commons and the country should be well informed upon the fundamental principles of army organisation advocated by Mr. Arnold-Forster if frequent insistence of them on his part can carry conviction. But unfortunately while there are a great many people who are quite ready to agree with the War Minister so long as he confines himself to dealing with generalities they want to know a great deal more about the practical working of his scheme than he is in a position to tell them, and in the meantime the state of the army is suffering from the present chaotic condition of things. The supply of officers, dissatisfied with the present state of affairs and full of uncertainty and misgiving as to their future, is falling off. As everyone knows there has hitherto been no lack of army candidates in this respect. It was in regard to the supply of the men that the lack existed and in the present state of public opinion regarding compulsory service it is likely to continue. In such circumstances it would seem desirable that every inducement should be given and every facility furnished for increasing the strength and raising the standard of the volunteer forces of this country. We have no hesitation in saying that no scheme of army reform will prove successful which does not take full account of the prominent part which the sanitary and medical branches of the army are destined to play in modern warfare. We fail to see that the present scheme does this. The question of army reform and reorganisation is no party question; it concerns not only this country but the whole empire and we are glad to notice a proposal that it should be referred to, and considered on that basis by, a body composed of the best men of both political parties with the aid of some naval and army experts.

THE FRENCH ARMY SYSTEM.

It may be interesting at the present time to know that the law authorising the adoption of a two years' service system has been definitely voted by the French Parliament. The new arrangement is that the Frenchman is to serve for two years in the active army, 11 years in its reserve, six years in the territorial army, and six years in the territorial reserve. The service will count from Oct. 1st in the year of entry.

THE WAR IN THE FAR EAST.

Beyond the fact that a part of the Japanese force is reported to have driven the Russians from Mien-hua-chich and to have occupied that village and the heights to the north of it the situation in other directions is unchanged. Although we hear nothing officially of the Japanese movements their armies are nevertheless said to be slowly advancing. There is no medical news. The weather has become warmer and the sufferings of the troops in this respect have been mitigated. The rumours of peace and of a preliminary armistice in consequence, which were so currently and confidently circulated last week, have died a natural death. We did not allude to them because we thought that such rumours were mainly explicable upon the assumption that "the wish was father to the thought," and we discredited the idea that in the then existing state of things Japan could consent to any suspension of hostilities.

Various statements have been made as to the losses suffered by the Russians at Mukden and in the retreat therefrom but they have all lacked official authority. In St. Petersburg the total casualties during the battle and retreat are set down at 105,000, while in Tokio double that number has been mentioned. According to General Trepoff, director of the medical service in Manchuria, the numbers of the sick and wounded sent to the rear of Tieling between Feb. 28th and March 14th were 1739 officers wounded and 433 sick; 56,723 men wounded and 4975 sick. Moreover, 800 wounded had to be left at Mukden, with two field hospitals and two Red Cross hospitals. The revised unofficial estimate of the Japanese casualties at Mukden and Tieling puts the figure at 57,000. The recent publication at Tokio of an Imperial message to General Kawamura and his force puts us in possession of information which clears up any doubt that might have existed regarding that army which is now officially designated as the army of the Yalu. It rendered signal service at the battle of Mukden by drawing off a large portion of the Russian forces to the north-east.

HEROIC SISTERS OF MERCY.

The correspondent of the *Russkoe Slovo* says that the conduct of the medical staff during the disastrous fight at Mukden merits special mention and constitutes a bright page in that sad story. Many medical men besides six Sisters of Mercy were seriously wounded during the engagement. Sister Chomiakoff specially distinguished herself. In front of Fushun she continued almost without help to bandage the wounded up to the last moment and only left the field after they had all been removed. For two days the Sisters, quite forgetful of self, fed the sick and wounded. Many did not sleep for days together, there being no room in the carriages for them to lie down. The young Sister Tatian Mirkovitch and the wife of General Sidorin for a time worked day and night without ceasing.

NON-PIERCING BULLETS INDUCING AGGRAVATED WOUNDS.

On the occasion of the meeting of the Pirogoff Society, St. Petersburg, held on March 15th, Professor N. A. Kaldiana communicated a report on the wounds inflicted in the disturbances on Jan. 22nd in that city. The wounded were taken to the Petropavlovsk Hospital. They consisted of 43 persons, of whom 20 were injured by bullets. The first aid consisted of antiseptic bandaging. The search for bullets and their extraction were delayed until first aid had been given to all the patients admitted. Many of the wounded after being bandaged went home to return on the following day for examination. The complications ensuing on injury by bullets were somewhat serious. Notwithstanding the short distance between the victims and the soldiers, about 200 or 300 paces, most of the bullet wounds showed only a point of entry. Professor Kaldian explained that this curious circumstance is to be attributed to the fact that the soldiers aimed at the lower extremities, so that the wounds were caused by ricochet. Some of the wounds appeared as though inflicted by splinters of bullets. Exact statistics of the numbers treated could not be furnished as the medical men engaged on the work were too busy to keep account. On the whole, most of the wounds followed a favourable course, all the sufferers having recovered.

Correspondence.

"Audi alteram partem."

THE "MICROBE DOYEN."

To the Editors of THE LANCET.

SIRS,—As the question of cancer is of interest at the present time I think it would not be amiss to state in a few words the position according to the researches of Dr. Doyen. Dr. Doyen has now made investigations for many years. In 1900 he obtained a culture of a microbe which he found in various cases of malignant tumour; he called it the micrococcus neoformans and was the more convinced that it was the true cause of cancer in that it differed from all other organisms with which he was acquainted. In 1904 he read before the Congrès de Chirurgie a communication in which he gave an account of 242 cancerous patients treated by means of his serum and claimed that 40 of them were greatly improved. This communication gave rise to much discussion and it was suggested that a committee of members of the Institut Pasteur and French surgeons should be formed to inquire into his microbe and the therapeutic value of his serum. That committee was not formed but Dr. Doyen requested Professor Metchnikoff to verify the bacteriological side of his researches. Professor Metchnikoff found the microbe present in several cases of tumours and that it presented the characters indicated by Dr. Doyen but he could not state that it was the microbe of cancer, his opinion being that many experiments must first be made. Dr. Doyen, however, was convinced that he had obtained experimentally tumours which resemble malignant tumours in man. He brought to Professor Metchnikoff numerous microscopical preparations obtained from animals in which he had inoculated his organism and which he thought gave a new proof that his microbe was the cause of cancer.

Professor Metchnikoff requested one of his assistants, Dr. Weinberg, to examine these preparations. After a very careful examination Dr. Weinberg came to the conclusion that although the lesions obtained were interesting he could not find in them the true character of a malignant tumour and was convinced that they were purely inflammatory. Dr. Doyen then wished to make a communication before the Académie de Médecine but the committee did not see fit to permit him to do so. He then showed his preparations before the Société Anatomique. It was decided that the members of the Société Anatomique should examine his sections in the laboratory of Professor Cornil and discuss the question at the next meeting. That discussion took place on March 17th, 1905, in the presence of Dr. Doyen and was continued on the 24th. It is not possible here to give a description of all his preparations, one can only say that the members of the Société Anatomique, represented by Professor Cornil, M. Brault and M. Letulle, decided after careful discussion of each section that not one of them could be labeled "malignant tumour." Dr. Weinberg reminded Dr. Doyen that he had come to the same conclusion when he examined the specimens at the Institut Pasteur. He had had occasion to make a bacteriological examination of many tumours and had frequently found the microbe Doyen but thought that it played a rôle in certain secondary inflammations of malignant tumours. As to the agglutinating action of the serum of cancer patients on the microbe Doyen he could not accept that as a new proof of the specificity of the microbe, for it was well known that we can obtain different agglutinins on injecting into the same animal at the same time [illegible] microbes, therefore he could understand [illegible] le to agglutinate [illegible] arasitic disease) [illegible] There can be no doubt that Dr. Doyen deserves much praise for the patience and perseverance he has shown in his investigations but unfortunately at present there is no evidence to prove that he has found the microbe of cancer. Professor Metchnikoff, in whose laboratory I have the honour to work, sums up the situation thus: (1) the microbe Doyen exists; (2) it is probably secondary, as streptococci, &c., are found in tuberculous cavities, and is not the cause of cancer; and (3) the serum obtained by its aid does sometimes ameliorate the condition of cancer patients in the same way that amelioration *may sometimes* be obtained by injection of sera obtained from other organisms.

I am, Sirs, yours faithfully,

April 3rd, 1905. R. STENHOUSE WILLIAMS, M.B. Edin., &c.

MEDICINE: ITS PRACTICE AND ITS PUBLIC RELATIONS.

To the Editors of THE LANCET.

SIRS,—Referring to your remarks made in Chapter VI. (p. 879) of "Medicine: its Practice and its Public Relations," with reference to the action of the Pharmaceutical Society against members of the medical profession in Scotland for the infringement of the Pharmacy Acts *by their unqualified assistants in pharmacy*, you do not seem to be aware that we appealed to the Privy Council, complaining of the action of the General Medical Council. That petition was sent by the Privy Council to the General Medical Council who recorded it in their minutes (1903 or 1904). The Pharmaceutical Society has not ceased action, as it has prosecuted a number of unqualified assistants of medical practitioners for the sale of poisons and I think in every case has obtained penalties. The General Medical Council, however, has taken no action in these cases. What is the reason of this I do not know.

I am, Sirs, yours faithfully,

JOHN BROWN, M.D., F.F.P.S. Glasg.

Glasgow, April 3rd, 1905.

To the Editors of THE LANCET.

SIRS,—Referring to the fifth very able article of your correspondent on "Medicine: its Practice and its Public Relations," I should like to point out, as a hospital reformer of some years' standing, that bare justice has been done only in relation to the hospital conference which was held at St. Martin's Hall *in October, 1899*. I was, of course, not responsible in any way for the speeches made on that occasion but I was altogether responsible for the various papers read. And I venture to say without any diffidence that the authors of the various papers were men who had had great experience of the subjects they wrote about; and, moreover, although many years have passed since their views were published, yet nothing fresh in any way has been given to the world with regard to the solutions of the many problems that they dealt with individually. I may be allowed to add that some of the recommendations made by the authors of the papers have been adopted by the authorities of the various metropolitan hospital funds. I may be pardoned for recalling to your memory the names of those gentlemen who so materially assisted at the conference by reading papers: Dr. F. J. Smith, Mr. Douglas Dent, Dr. Arnold W. W. Lea, Mr. G. Hawkins-Ambler, Colonel Montefiore, Mr. G. A. Wright, Dr. Bertram M. H. Rogers, and Mr. C. W. Warren.

I am, Sirs, yours faithfully,

Cardiff, March 29th, 1905. T. GARRETT HORDER.

To the Editors of THE LANCET.

SIRS,—I am obliged to you for allowing me to see these letters. Some of the names which Mr. Horder enumerates belong to gentlemen honourably known for their work and far be it from me to suggest that they or any other speakers did not know their subject *au fond*. All that I intended to convey was that certain of the speeches did not bear out this view.

I knew, of course, of the action of the Privy Council but not of the continued prosecutions to which Dr. Brown alludes. I am, Sirs, yours faithfully,

THE AUTHOR OF THE ARTICLES.

THE RATIONAL TREATMENT OF FRACTURES.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of March 4th, p. 601, "Dubitans," in the course of commenting on the method of treating fractures, as strapping, rubbing, and movement, asks me two questions. First, as to whether I should use extension in the case of oblique fracture of the bones of the leg—i.e., the femur, the tibia, and the fibula—I would in reply say that in fractures of the femur I like to use, and have up to now found efficient, the double inclined plane or Liston's long splint with perineal band, according to the position of the fracture, but in either case following out the strapping, rubbing, and movement. As regards the fracture of both bones of the leg the case which I described was oblique in nature and did very well with strapping and Cline splints. I certainly am of opinion that strapping helps to hold the bones in position and checks riding to a great extent. In a bad case of oblique fracture of this kind, if I found Cline splints and strapping were insufficient to keep them in position, I should place the limb, after strapping, on a back splint with side splints and sling it in a Salter's cradle. Personally I seldom try to adjust the position of a bad fracture at once accurately, as it is far better to wait until the inflammatory effusion has settled to some extent and is beginning to be absorbed. Rubbing will hasten this greatly. By delaying the "setting" in this manner for some days the spasmodic contraction of the muscles will have subsided to a great degree. It is quite possible that one might see a very oblique fracture that would get out of position directly a splint is removed. If I were to find a fracture do this in spite of the strapping I should not remove the restraining influences until some union had occurred but were this fracture in a position to allow the joints above and below to be used daily while supporting the fracture with short splints I should certainly make use of some form of splint which would permit the joints to be moved and begin rubbing as soon as there was some degree of union.

The second question is as to whether the generalisation of so-called rational treatment from simple cases of fracture is dangerous when applied indiscriminately elsewhere and is there any other rational treatment in the troublesome cases than bone carpentry by cutting down upon, and securing together, the fragments, as in Mr. W. A. Lane's plan? As to the first half of this question, the term rational treatment was not meant to be dogmatic and if taken in the narrower sense might be dangerous. As regards the bone carpentry I admit that there may be some cases of oblique fracture where, in spite of all the care possible, the result will still be unsatisfactory.

I believe that in these cases Mr. Lane's treatment is the right one but I do not think that this method can be of general use in practice. The operations are not so easy in the most happy circumstances and would be practically impossible to carry out and to keep aseptic in many small houses and cottages, even supposing the patients were willing to allow it. In country districts the patients will solve the problem for one. They are not likely easily to submit to "an operation for a broken bone" as they would term it. You would probably find yourself dismissed in favour of a surgeon who has not expressed any desire to use the knife to mend the leg; and from the surgeon's point of view I think this is an operation which should only be undertaken in aseptic surroundings and patients are loth to leave their homes for hospitals on account of broken limbs. Even among the better classes where the surroundings are suitable I think that there would be an almost insuperable objection on their part to operation on simple fractures. In compound fractures this objection would not be so great. Circumstances alter cases and what might be the rational treatment in one case would be quite unsuitable in the other, and fortunate is the surgeon who can adapt himself to the surroundings of each individual case; but I certainly maintain that the rational treatment of any fracture, where it is possible to use it, is by the method of strapping, rubbing, and movement, as early as possible, consistent with a good result.

I am, Sirs, yours faithfully,

March 17th, 1905. J. STAFFORD MELLISH.

IF TUBERCULOSIS SHOULD BE CERTIFIED, WHY NOT SYPHILIS?

To the Editors of THE LANCET.

SIRS,—I never heard of phthisis causing syphilis but I believe that many thousands of cases of phthisis are caused by syphilis. And considering that there are thousands of cases in our lunatic asylums caused by syphilis and that our hospitals have thousands of cases of heart and kidney disease, brain disease, blindness, deafness, skin disease, and disease of almost every organ caused by syphilis, would it not be well if we went to the *fons et origo* and formed a national association for the prevention of venereal disease. By so doing I believe that we should enormously decrease the amount of phthisis. I see that at the sixth general meeting of the National Association for the Prevention of Consumption Sir William Broadbent and others urge that public authorities and public money should be used for establishing sanatoriums for consumptives. But is this a wise use to put public money to? Ought not it to be used equally for the prevention and cure of syphilis? For I believe that the sanatorium cure and open-air cure are just as efficient against syphilis as against phthisis and just as necessary. Every syphilitic is a danger or a burden to the State "even unto the third and fourth generation." And he is, if he is not cured, a fertile soil for the tubercle bacillus and its propagation and distribution. Again, why should medical men certify cases of phthisis and not cases of syphilis? Why should chicken-pox and small-pox be certified and not great pox? It seems to me that taking all the speeches at the meeting referred to you might substitute syphilis or venereal disease (for the ravages of gonorrhœa are staggering also) for consumption or tuberculosis and they would be of equal, if not of greater value—e.g., "If the Metropolitan Asylums Board would undertake to deal with syphilis (or venereal disease) which was to a certain degree a contagious disease, they would leave a very distinct impression upon the amount of that disease which existed in London and not merely save life but promote the public health," &c.

I honestly believe that if we could stamp out syphilis and gonorrhœa we should diminish by one half the amount, not only of phthisis and infantile tuberculosis, but of kidney disease, gynæcological disease, bone, eye, ear, skin, brain, spinal cord and, in fact, most diseases and much diminish the amount of cancer. Then why in the world do we not do it?

France has now given us the lead. France, taught by experience and startled to wakefulness by M. Brieux's play and the efforts of *Le Matin*, has formed a "National Association for the Prevention of Syphilis." It will distribute literature and by education will try to prevent the ravages of syphilis caused by ignorance and neglect. Why does not England do the same? I believe that venereal disease has more to do with the physical deterioration of the race and degeneracy than primary tuberculosis has. The majority of the submerged tenth are, according to my experience gained in hospital out-patient departments, syphilitic, many of them hereditary. They are good for nothing and never will be good for anything. Our workhouses and casual wards are half full of them. The army and the navy are gravely (how gravely it is shocking to think) affected. Our seaport towns are rotten. And what do we do to prevent the spread of it and all its attendant evils? Nothing, almost nothing. And why? Because we say we must certify tuberculosis, or scarlet fever, or chicken-pox, or small-pox, but great pox, more deadly than all, No—we let that go as it pleases. And why? Largely because we do not like to talk of disagreeable things; and also there is a curious pseudo-puritanical spirit which will not allow the innocent to be protected with the guilty and shuts its ears and eyes to the cry of millions of sufferers because its curiously perverted "conscience" seems to teach that "pox populi" is "pox Dei." Will our profession not give the lead towards a better state of things, now and soon? I am, Sirs, yours faithfully,

Cannes. EDWARD H. DOUTY.

"AMAAS."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of May 7th, 1904, p. 1273, appeared a clinical description of a disease called "amaas" occurring in South Africa, said to be allied to, but to differ from, small-pox. The author, Dr. W. E. de Korté, again in your issue of Dec. 24th, 1904, p. 1776, speaks of "amaas" as a distinct disease. He appears to base his differential diagnosis on the possibility of vaccinating persons who have recently suffered from "amaas," that it has a low mortality, that there is no secondary fever, and on the character of the scars and marks which the disease leaves behind it.

I intended last year to criticise Dr. de Korté's paper but pressure of work prevented it. However, I send you a copy of the report of the medical officer of health of the Colony of the Cape of Good Hope for the year 1895 which contains an investigation into the nature of a disease said to be "amaas" which prevailed in and around Graaff Reinet. Dr. de Korté was then practising in Graaff Reinet and it is to be presumed that the disease which he now calls "amaas" is identical with that to which he then gave that name and which proved to be ordinary small-pox.

With regard to the possibility of vaccinating after an attack of small-pox with calf lymph I may state that I myself had small-pox; two or three years after I purposely inoculated myself with small-pox without any effect, yet afterwards while vaccinating calves I accidentally inoculated myself and very typical vaccinia resulted. The existence of "amaas" depends upon a mistaken diagnosis based upon inaccurate clinical observations.

I am, Sirs, yours faithfully,
GEORGE TURNER,
Medical Officer of Health, Transvaal.
Public Health Department, Pretoria, Jan. 30th, 1905.

*** The report for the year 1895, which Dr. Turner sent to us as above mentioned, forms with its appendices a bulky document of 156 printed pages. Dr. Turner was at that time himself the medical officer of health of the Colony of the Cape of Good Hope and the principal or introductory report is naturally signed by him. Under the heading of "Small-pox" he says on p. 14: "This disease, so much dreaded, gave rise to very few deaths during the year 1895. It was, however, prevalent at Kimberley and in some other districts. It was of an exceedingly mild type, attacked the natives chiefly, and was therefore often described as chicken-pox, amaas, &c. The reason why the malady was principally confined to coloured persons was undoubtedly due to the fact that these were much less protected by vaccination than the Europeans. ...... Twice for about a week on each occasion I had an opportunity to see small-pox amongst the natives at Taung and I watched carefully to see if the disease in any respect differed from small-pox as I had seen it in Europe, especially during the great epidemic of 1870-72, but could not discover any essential difference. I had frequently heard the opinion expressed that a disease did prevail amongst natives which closely resembled small-pox but which was not that disorder. I was therefore particularly anxious to meet with cases of this kind and gladly received instructions to proceed to Graaff Reinet, where I was informed that a disease resembling, but not identical with, variola prevailed." The results of Dr. Turner's inquiries at Graaff Reinet are given at length in Appendix II. of the report. It consists of 12 printed pages and, in addition, contains reproductions of photographs of five patients showing the eruption, seven temperature charts, and a plan of a court in Graaff Reinet where some of the patients lived. This appended report is dated "Cape Town, Cape of Good Hope, 19th March, 1896." After eight pages of clinical descriptions of patients Dr. Turner says that the cases designated "amaas" at Graaff Reinet were "unmistakeable discrete small-pox, such as is commonly met with in Europe, Asia, America, and elsewhere." As far as he could discover the diagnosis of "amaas" and its discrimination from small-pox were based upon the following points—namely (1) that the eruption after the scabs have fallen leaves pigmented marks and does not pit; (2) that the eruption appears sooner after the commencement of the prodromata than would be the case in small-pox; (3) that the death-rate has been low; and (4) that "amaas" does not attack Europeans. In discussing these arguments against the identity of "amaas" and small-pox he maintains that they are all untenable.—ED. L.

A QUESTION OF SITE.

To the Editors of THE LANCET.

SIRS,—As the future of the Institute of Medical Sciences becomes more hopeful its practical details acquire an importance which it was formerly unnecessary to give them and to my mind one of the most important things to discuss is whether South Kensington is the fittest place for such an institute. It may be that the authorities are committed to this site; if so it will be well to realise the disadvantages connected with it in order that they may be, as far as possible, counteracted. I am only able to offer an expert opinion as a teacher of anatomy but from that point of view I feel that the distance of the proposed institute from the clinical centres will be a serious handicap. It is only lately that I have realised how largely the dissecting room of a hospital is used by students before their final examinations in surgery and how usual (and often necessary) it is for candidates preparing for the Primary Fellowship to combine a certain amount of clinical work with that preparation. Then it is undoubtedly an advantage to all concerned that the whole of the teaching should not be in the hands of professional anatomists, that some of the demonstrators should be young physicians and surgeons who can give a certain amount of their time to the dissecting room. Again, the nearness of the anatomical department to a post-mortem room is an advantage which is only fully appreciated when anatomy has to be taught in an institution where no post-mortem room is.

Those of us who have many committees to attend at South Kensington know how much time is wasted in the journey there and back from the centre of London and I feel sure that the proposed institute there will be seriously handicapped in competing with others more favourably placed as well as with those hospitals which elect to keep their anatomical and physiological departments as at present. If the University could extend its agreement with the Royal Colleges and use the Embankment premises for teaching as well as for its examinations, it would, from the point of view of anatomy, be much more convenient. Failing this, is it too much to hope that some influential body will come to the help of London medical education and grant a more central site? If the new institute is so remote that the schools cannot concentrate there conveniently the result will be that yet another centre will enter into competition with those already existing (and more favourably placed) and it will need all its proposed endowment in order to survive.

I am, Sirs, yours faithfully,

St. Thomas's Hospital, March 28th, 1905. F. G. Parsons.

TYPHOID FEVER IN LINCOLN.

To the Editors of The Lancet.

Sirs,—In the various papers recently written on attacks of typhoid fever past and present in Lincoln, I have not seen any account of the severe outbreak of typhoid fever that occurred in 1857. In that year I called public attention in the local papers to the sanitary state of Lincoln—there was no main drainage, the sewage ran into cesspools which soaked into the surrounding soil, poisoned the water of the pumps, and caused the most disagreeable smells all over the town. According to the Medical Directory of 1856 the population of Lincoln was 17,536, but the number of cases and the mortality then were proportionately as great as in the present epidemic of typhoid fever of 1904–05. The main drainage was accomplished about 1882; it had an immediate beneficial effect on the health of the inhabitants of the city and the benefit would have been much greater if provision had been made for flushing the sewers. In rainless warm weather, especially if fogs prevail, the sewers become very offensive and the effluvia that escape from the manholes cannot fail to have injurious effects on the inhabitants of the houses situated close by. I think it was an Irish judge who first drew attention to the danger of manholes. He noticed that the people who lived in houses contiguous to a certain manhole in the neighbourhood of his residence were nearly always ill or ailing.

The nose generally gives the warning note of danger, but the mouth is the great open door which admits free trade in all kinds of seeds of epidemics, not always the only one, for sometimes they gain admittance through the back door. I have a sad case of this kind imprinted on my mind. An uncle of a lady who kept a boarding school for young ladies came to pay a visit of a few days to his niece. He was recovering from typhoid fever and in the night was attacked with diarrhœa and the excretions were thrown into the water-closet that was used by the young ladies. In a short time typhoid fever of a most virulent character broke out in the school and five or six of the girls died.

I attributed the outbreak of fever in 1857 to emanations from foul sources, overcrowding of small dwellings, and many other causes. I caught the fever myself and believed it to be the result of a defective water-closet. The Lincoln water did not seem to have been much blamed in the production of the disease at that time, nevertheless I drew attention in one of my letters to the danger of drinking water into which sewage ran and gave as examples that Dr. J. Barry of Cork stated that such of the inhabitants of that city who drink the water of the river Lee, which receives the contents of the sewers, are subject to a most fatal dysentery and fever and that one out of every three affected dies from it and also that the water of the river Seine at Paris often produces fever and dysentery and as a consequence of this suppurative inflammation of the liver. I may mention that the Lincoln water-supply was formerly in the hands of a company. The company took the water that was close at hand, that is, from the Witham and from pools formed by water that ran off the fields. The two made an unhappy "blend" which has not yet been rectified. When the Romans occupied Lincoln doubtless the Witham was here and so were the pools of water but they very wisely did not take their drinking and cooking water from them but went three miles out of the town for it to the springs at Nettleham and conveyed the water to Lindum Colonia through well-made fayence pipes which were laid in beds of strong cement. The great desideratum with Lincoln now is pure water. The corporation is boring for it and it is to be hoped it may get it but I am afraid that in the end it will have to go for good water to the Wolds. In the meantime for drinking water we have to live on the charity of the benevolent of neighbouring towns.—I am, Sirs, yours faithfully,

William O'Neill, M.D. Aberd., M.R.C.P. Lond., &c.

Lincoln, March 14th, 1905.

SCURVY RICKETS.

To the Editors of The Lancet.

Sirs,—The milk-supply of metropolitan public institutions is rarely beyond reproach. Managing boards usually accept the lowest tender and unless there is some glaring deficiency of cream or some unusually apparent staleness the difficulty of rejecting an unsatisfactory delivery is very great. Practically all milk is railway borne and consequently is much contaminated by dust and other filth. As delivered there are always a perceptible scum of light dust on the surface and a variable layer of coarser particles of dirt at the bottom of the churn. In such circumstances sterilisation of the milk before issuing it to the children is imperative. Some time ago, owing to the occurrence of some slight cases of scurvy rickets, I suspended the sterilisation by heat and tried the effect of formic aldehyde in varying proportions. I observed that some infants could tolerate the formic aldehyde for a time, even to the extent of ten parts per 100,000, whilst others showed undigested curds in their stools even when so low a proportion as one in 100,000 was used. This evidence of increased difficulty of digestion of the curd necessitated a return to the heat sterilisation, with the addition of the juice of an orange or of a portion of a banana daily, and if this addition be regularly given I believe scurvy rickets will not arise. All the cases I have met with have occurred in children who have been fed exclusively on boiled milk.

The first symptom noticed is the evident pain which movement causes the child; examination shows the existence of brawny swelling of the thighs, upper arms, shins, and forearms, these parts being affected in the order above given. Occasionally hæmorrhages occur in other places. I have seen a case in which the first noticed symptom was a pronounced black eye accompanied by considerable proptosis and external squint. A subsequent necropsy revealed the presence of a large hæmorrhage under the periosteum of the orbital plate of the frontal bone. Complete separation of the epiphyses from the shafts of the long bones is of frequent occurrence and post mortem the periosteum is found to be separated from the shaft of the bone by a blood clot varying in extent and thickness. The immediate substitution of an unboiled milk may save the child. I remember a little girl who had the lower epiphysis of both humeri separated and yet survived. Still, the mortality is very heavy. The point to which I desire to draw special attention is the possibility, and even likelihood, that manifestations of this disease may be attributed to violence. The appearances are very similar. The swelling, the possible ecchymosis, the signs of the broken bone, would certainly suggest the application of undue force to the lay mind and might even deceive the medical attendant, especially if accompanied by a tale of ill-treatment. In wo of my cases the correct diagnosis of the condition alone prevented a charge of cruelty being brought against perfectly innocent persons, and in these days when members of public bodies apparently possess unlimited and unpunishable powers of irresponsible criticism and accusation, and when societies base their claims for support upon the number of convictions obtained by them, it behoves medical men to bear the symptoms of scurvy rickets well in mind when called upon to examine cases of alleged injury to young children.

I am, Sirs, yours faithfully,
F. S. TOOGOOD, M.D. Lond.,
April 3rd, 1905. Medical Superintendent to Lewisham Infirmary.

PRESSURE STASIS.

To the Editors of THE LANCET.

SIRS,—The interesting case of extreme compression narrated in THE LANCET by Dr. R. Lane Joynt reminds me of a similar case which I treated a few years ago. A party of 30 or 40 excursionists were proceeding in a four-horse break from Manchester to Chester to see the "Chester Cup" run for. A wheel came off, the [illegible] toppled upon somebody e[illegible] women came off especially [illegible] lodgings in Chester (the accident had occurred three or four miles away) and I saw them as soon as they arrived. The one, rather stout, 48 years of age, had a comminuted fracture of the middle of the right humerus and a fracture of the left clavicle; but what struck me most was the extraordinary appearance of her eyes, the whites were bright red, the whole of the conjunctivæ of both eyes being suffused with blood. Her face and forehead, ears, neck, and part of her chest were bright red. There was also a small occipital scalp wound and a little blood had been squeezed out of the right ear. Her friend had a broken leg and some bruises. The subsequent progress of the two patients was (happily) uneventful. The ecchymoses, bruises, &c., passed through the usual colour changes, the fractures united, and the patients were able to go home in a fortnight with their fractures in "plaster." They came to see me at intervals and completely recovered.

I am, Sirs, yours faithfully,
Chester, April 2nd, 1905. HENRY W. KING.

THE TREATMENT OF EMPYEMA.

To the Editors of THE LANCET.

SIRS,—Daily irrigation as a method of treatment of empyema is an anachronism. I should not have thought that anyone employed it at the present day. Certainly I do not, as Mr. Godlee assumes. The pleura may be washed out at the time of operation with advantage if the pus be fœtid or too thick and curdy to be easily evacuated; but if the pleural cavity be once thoroughly cleansed subsequent washing out is *rarely required*. The only object I had in my paper in referring to washing out at all was to try to dissipate the fear which still appears to haunt the minds of some operators that it involves great risk of fatal collapse. For this purpose it was necessary to speak of my own experience, which happened to be considerable on that point, for when a student at St. Bartholomew's Hospital and subsequently when resident at the Chest Hospital, Victoria-park, frequent washing out was a method of treatment of empyema much in vogue with some of the older physicians. I thus had an [illegible] of washing the pleura out and of [illegible] times, probably, as I said, some [illegible], *as Mr. Godlee makes me say*, in some hundreds of cases. I never saw any bad symptoms produced and therefore I consider the risk infinitesimal and one that may be practically disregarded.

To excision of rib my objection is not so much that it adds something to the operation as that it weakens the framework of the chest, especially if a portion of more than one rib be removed. Drainage can often be perfectly provided for without it and therefore I do not consider excision necessary as a routine practice. I quite agree with Mr. Godlee that the drainage-tubes used are often too long, but even a short tube will generally require more shortening [illegible] the incision [illegible] be in the seventh or if a little farther forward in the sixth space, but by no possibility in the fourth, as Mr. Godlee says it might.

The use of the probe in exploring the pleural cavity enables us to ascertain the size, the limits, and the relations of the cavity. In the early days after the operation, if the case is [illegible] at our disposal of ascertaining the exact conditions of things within the thorax and often enables the defect to be remedied without recourse to further operative measures. As careful examination with a probe can do no harm I cannot sympathise with Mr. Godlee's objection to it. I do not think, after all, that Mr. Godlee and I differ seriously in our views of the treatment of empyema and certainly not so gravely as he implies.

I am, Sirs, yours faithfully,
Wimpole-street, W., April 3rd, 1905. SAMUEL WEST.

LEGISLATION FOR FEMALE CLERKS.

To the Editors of THE LANCET.

SIRS,—Will you kindly grant me a short space in your columns to bring again before the notice of the profession the urgent need for legislating for the protection of the health of the large and increasing number of female clerks employed in London and other centres. The Factory Acts safeguard the interests of women engaged in workshops, but there is absolutely no control over the employers of women engaged in clerical work. Three cases have lately come under my care which I would like to call attention to, as they illustrate the disabilities under which this class of workers suffer. A lady recently consulted me and during the interview she told me that she was engaged as a typist to a well-known solicitor. Ten women are employed by the firm and there was no lavatory accommodation whatever for the women. When they wanted to relieve themselves they went out to a railway station near. I suggested that I should write to her employer on the subject, which was agreed to. I received a very polite note from the gentleman stating that he had not given the subject a thought but promised that the omission would be rectified immediately. In another case a young lady was suffering with a foul ulcerated throat. She told me that she was employed in a newspaper office with two other girls. They worked in a room at the end of a passage with no outside window. Just outside the door, which was constantly being opened and shut, was the men's lavatory, which seems to have been always in a most filthy state. The third case is that of a young woman engaged in a similar occupation whose working hours lasted from 9.30 to 8.30 usually but at certain periods of the year, in all amounting to two months, they were kept until 11 P.M.

If three such cases occur in the experience of one practitioner in a short time, what must be the aggregate amount of suffering of a preventable nature the thousands of women must have to endure who go up to the City every day. I could quote other instances of a similar kind but I consider the above sufficient to call attention to three obvious defects.—I am, Sirs, yours faithfully,

T. E. WHITE, M.D. Durh., D.P.H.
Catford, S.E., April 3rd, 1905.

SHOCK AND COLLAPSE.

To the Editors of THE LANCET.

SIRS,—Mr. C. Powell White in his letter in THE LANCET of April 1st, p. 887, draws attention to my statement that "the blood pressure is maintained within a few degrees of the normal range even under extreme variations in outside pressure" and points out that this is incompatible with the treatment of patients suffering from shock by compressed air. The statement referred to is, of course, only meant to apply to a healthy individual whose vaso-motor system is uninjured. Mr. White has not appreciated the distinction which I drew between the normal physiological condition of the circulation in health and the morbid physiological condition which exists in shock. Directly the vaso-motor system has broken down and become incompetent, as is the case in shock, the statement no longer holds good and the blood pressure tends to follow any variations in outside pressure.

When a patient is suffering from shock increasing the atmospheric pressure will raise the blood pressure.

cause of the lowered arterial pressure in shock is the increased capacity of the vascular system resulting from loss of vaso-motor control. Increasing the atmospheric pressure will diminish the capacity of the vascular system and so directly raise the blood pressure in the essential part of the circulation—namely, the heart and great vessels and the brain. I am, Sirs, your faithfully,

April 4th, 1905. P. LOCKHART MUMMERY.

FREE INCISION IN PLEURITIC EFFUSION.

To the Editors of THE LANCET.

SIRS,—In your issue of March 25th I notice that Dr. S. West discourages "free incision" in pleuritic effusion. As I have treated a few cases in this manner with success I would like to express my opinion with a view to encourage this method of treatment. I have employed incision in acute cases, sometimes with a high temperature and pneumonia. The object of the treatment is primarily to relieve the dyspnœa and secondarily to prevent the adhesions which are so frequent after empyema, not to refer to the very large number of cases which go on to tuberculosis. Dr. West says: "The objection to this method of treatment is, of course, that it necessarily leads to empyema." My experience is that it is more probably a preventive of empyema, if the drainage is properly carried out. If done early, within a week or so, there is no fear of adhesions, as Dr. West anticipates. It is supposed to be the relief of tension that cures, as similarly occurs with an obstinate effusion in a joint when incised. Far from being "unjustifiable" as a method of "radical treatment" I think it appeals to anyone on first principles and as the lung expands quickly there is no cavity left to become septic.—I am, Sirs, yours faithfully,

Hampstead, March 28th, 1905. ALBERT WILSON.

ISOLATION HOSPITALS.

To the Editors of THE LANCET.

SIRS,—Allow me to assure Dr. F. Lucas Benham that I sincerely regret having misread his former communication to THE LANCET and that the part of my letter in which I offered him my congratulations on his having "contented himself with a letter to THE LANCET" should have been so badly worded as to have given the impression that I was harbouring an *arrière pensée*. What I intended to convey was that continued association with this movement would have brought him no more satisfaction than it has brought us. As Froude has it, "Men possessed with an idea cannot be reasoned with"—which explains the fact that after 25 years of continuous failure the isolation hospital still exists, but the why and the wherefore of its existence nobody knows.

I am, Sirs, yours faithfully,

Nottingham, April 1st, 1905. EDWD. DEAN MARRIOTT.

IMMIGRATION AND THE DEATH-RATE.

To the Editors of THE LANCET.

SIRS,—In your comments on the Registrar-General's sixty-sixth annual report it is stated that "it is unreasonable to expect that in a country receiving hordes of destitute aliens from all parts of the world the present exceptionally low death-rate will be permanently maintained."[1] It would be interesting to learn what is the writer's conception of a horde. I may say at once that the immigrants do not dwell here in tents, camps, &c. As to numbers, there were in 1902 probably less than 56,000[2] and in 1903 considerably less than in 1902.[3] They are certainly not all destitute. THE LANCET annual returns show that in the districts with the largest number of aliens (Stepney) the death-rate is not the highest in London, neither for all classes nor for children under one year of age.[4] Mr. Charles Booth believes that an influx of foreign Jews, who, as is well known, form the bulk of the immigrants, will be a factor in reducing the death-rate in St George's in the East and Shadwell as it has been in Whitechapel.[5]

I am, Sirs, yours faithfully,

Commercial-road East, April 3rd, 1905. M. D. EDER.

THE SCAVENGERS OF NEW YORK.

THE OUTBREAK OF CEREBRO-SPINAL MENINGITIS; THE REMARKABLE INCREASE OF CANCER, ORGANIC HEART DISEASE, AND CHRONIC BRIGHT'S DISEASE.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

So many cases of cerebro-spinal meningitis have recently occurred in New York that the disease has assumed an epidemic form. Its presence has created very great alarm and not a few persons have already sought safety in flight. According to Dr. G. B. Fowler, who was recently commissioner of health of New York, this is a filth disease. In times gone by it used to prevail in prisons and also among the insane of filthy habits who were locked up in asylums that were a sort of prison and where no great care was taken to maintain cleanliness. To-day, however, there is a sanitary code issued by the board of health of the department of health of the city of New York. The corporation has a large budget and quite an army of officials and servants. Indeed, some of these are organised on a military basis. Filth, therefore, should not abound in such a city—at least, not to the extent of causing an epidemic similar to those which prevailed within the asylums and prisons in the days when little or no knowledge of sanitation existed. It must be confessed, however, that the scavenging and the paving of the streets are not what they should be. Though I was but a short time in New York still I came upon a few places where the pavement was in a deplorable condition and noticed about the streets a good deal of garbage which should have been removed. Such experience, however, is too limited to form the basis of an opinion. A few cases of neglect could be found in any town and I am not in a position to say whether what I chanced to see at New York was exceptional or general. On the other hand, at the University Settlement in Eldridge-street, which is on the East side and the most densely populated part of New York, I heard a lecture on this very subject. The lecturer described the measures taken by the late Colonel Waring and how he had insisted that he was determined to clean the streets.

For this purpose the colonel, who was the city commissioner for street cleaning, put his men into uniforms. He endeavoured to make them take a pride in their work and proclaimed what has often been said though not often realised—namely, that the scavenger is one of the most useful and indispensable functionaries of the State. He urged that it was not a disgrace to sweep the streets; the real disgrace was to take money for sweeping and then not to sweep. Having organised his scavenger brigade, given them their uniforms, and drilled them a little, he determined to raise their sense of self-esteem by some striking demonstration. It so happened that at that time there was a fashionable horse show. Consequently he had all the horses in the employ of the street cleansing department carefully groomed and decorated with ribbons. The men were told to put on their best and cleanest uniforms. Colonel Waring, himself in a similar uniform and mounted on a fine charger, rode at the head of the scavenger brigade, conducting them and their horses to the horse show. Here the fashionable and wealthy members of New York society, struck by the originality of the proceeding and realising the importance of the object in view, gave the scavengers an enthusiastic ovation. They had been accustomed to parades of firemen, but, after all, is not the scavenger as useful a worker? Does he not also largely contribute to protect the public against the dangers that especially menace the dwellers in large towns? It was certainly an excellent idea to endeavour to raise the standard of life and self-respect among the scavengers and Colonel Waring very ingeniously discovered a method of achieving this end It is essential for the welfare of the community that scavengers should realise how very important is the work with which they are entrusted and how serious the consequences may be if it is not carefully, punctually, and efficiently performed.

If, as it is maintained, cerebro spinal meningitis is a filth disease, can it be that since the death of Colonel Waring there has been some relapse and that the scavenging work is no longer so well done? Or is it, as the present commissioner says, that there is a great increase of street stalls, street markets, and costermongers' carts? In America all these itinerant vendors are known under the graphic and generic term of "push-cart" men, and they not only to a large extent fill up the streets but the refuse of what is sold is thrown on the ground and adds to the dirt and untidiness of the thoroughfares. This is particularly objectionable when the refuse consists of vegetable matter. Dr. Darlington, chief of the health department, has given figures showing that there is a higher death-rate than elsewhere in the "push-cart" streets, that is, the thoroughfares where street markets are held. This is attributed to the greater amount of garbage lying about and to the fact that the children have less space to play in, the street which constitutes their principal playground being more crowded and not so clean. A great improvement, however, was effected when asphalt was employed, particularly as care was taken to lay it down in the poorest streets first. The children, therefore, were able to play on a comparatively dry and non-absorbent ground that could easily be washed and scoured with the fire-hose. But, nevertheless, the costermongers' carts and the garbage thrown out of these carts at least superficially soil the streets in spite of the asphalt.

Formerly only old people were allowed to hawk goods in the streets. Now not only are there broken-down old people offering boot-laces to the passers-by but young vigorous folk bring along hand-carts full of boots and shoes to sell. Others sell hosiery and underlinen—in fact, everything and anything is brought into the street and offered for sale. The tendency seems to be to replace shops by an open-air bazaar. Such a transformation renders it much more difficult to keep the streets clean and has a decidedly injurious effect upon health. Then when the frost comes a certain amount of organic matter is, as it were, imprisoned in the ice that forms in the streets. There it may remain for weeks; but when a thaw comes it decomposes very rapidly. As the thaw affects the entire city and as it is not possible to clean simultaneously every part of the city, some mischief may arise before the appearance of the scavengers. Though nothing is really known as to the cause of the present epidemic, suggestions have been made that the condition of the streets, the difficulty of organising efficient scavenging when so many streets have been converted into markets, is a contributory cause. However this may be, it is undoubtedly a fact that while the diseases—mainly the zymotic diseases, which used to be the principal cause of high death-rates—are being gradually eliminated or very materially reduced in prevalence and fatality other complaints are increasing. This is all the more alarming as no satisfactory explanation is forthcoming. To-day there is the serious epidemic of cerebro-spinal meningitis which is said to have caused at New York alone some 700 deaths. But more serious because it is spread over a large number of years is the fact that New York shares with most other centres of population both in America and Europe in the growing prevalence of cancer. The New York board of health, however, is not particularly concerned with this statistical demonstration because, on the whole, the nominal augmentation in the number of deaths may be due to more accurate diagnosis rather than to a real rise in the number of cases of cancer. What is considered even more serious is the remarkable increase of deaths from organic heart disease and chronic Bright's disease.

To deal with cancer first, there were 2608 deaths ascribed to this cause at New York in 1903 and this is equal to a death-rate of 699 per 1,000,000 of the population. In 1902 the proportion was 674 per 1,000,000. But what is more important is that in 1873 the proportion was only 433 per 1,000,000. The increase from 1873 to 1903 is equal to 77 per cent. But it is pointed out in the official reports of the health department that in the old city of New York in 1873 the percentage of deaths from external cancer was 28 and from internal cancer 72 of all deaths from this disease. In 1902 the figures for the borough of Manhattan show that the proportion of external to internal cancer was 16 to 84. In 1873 the deaths from cancer of the breast were 13 per cent. and from cancer of the stomach, liver, and intestines 40 per cent. of all deaths from that disease. In 1903 the more obvious cancer of the breast caused only 9 per cent. of the deaths, while 53 per cent. of the deaths were attributed to cancer of the stomach, the liver, and the intestines, where the presence of cancer is not so easy to detect. Again, in 1873 28 per cent. of deaths from cancer were due to cancer of the female genital organs and in 1903 the percentage was only 16·4. In 1873 the number of males dying from cancer was 33, as compared with 67 deaths of females from this cause, but in 1903 the deaths of males was 40 per cent. and that of females only 60 per cent. of the total, though the numerical ratio of the sexes varied only 1 per cent. The average age at death of both sexes, based upon five-year periods, was 48 years in 1873 and 51·8 years in 1903. The increase of deaths attributed to cancer amounts to an average of 423 deaths per annum and per 1,000,000 of the population during the ten years 1873–1882. During the period 1883–1892 it was 554; during that of 1893–1902 it was 642. But this apparent aggravation is due to the more accurate detection of internal and inaccessible cancers and occurred among males rather than among [illegible] though it is not as extensive as is generally supposed, the New York department of health seems to be tempted to attribute the cause to the greater consumption of alcohol, tobacco, and meat together with the wider prevalence of syphilis.

In regard to the deaths caused by organic heart disease and by chronic Bright's disease, there are a few more due to the former than to the latter cause. Thus, for instance, there were 615 deaths from the former disease and 534 from the latter disease in 1868, the first year given in the statistics now issued. The important fact is that these figures increased in 1903 to 3129 and 2818 respectively. The augmentation of the population does not suffice to account for this. The death-rate due to both diseases amounted in 1868 to 13·50 per 10,000 inhabitants. The proportion in 1903 was 27·20 per 10,000 inhabitants. There have been some fluctuations in this increase and the last figure given does not represent the maximum. It was in 1870 that the proportion exceeded 15 per 10,000. In 1882 it exceeded 20 per 10,000. In 1891 it went beyond 25 per 10,000 but remained below that figure from 1894 to 1899, varying from 22·38 to 24·53 per 10,000. In 1900 the proportion was 25·32; in 1901 it rose to the maximum of 29·11; in 1902 it began to fall and was 28·11 and, finally, as stated before, there were 27·20 deaths per 10,000 inhabitants attributed to chronic heart disease and chronic Bright's disease in 1903. It will be seen, therefore, that in the course of from 30 to 40 years the deaths due to organic heart disease and chronic Bright's disease have more than doubled. Then we have the apparent, and probably, though to a less extent, real, increase of the prevalence of cancer and finally there is the actual and alarming epidemic of cerebro-spinal meningitis. These are facts and I mention them because they are important facts, not because there is necessarily any co-relation between them.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The Hospitals.

A FURTHER series of annual reports from the Birmingham hospitals has been published. It includes those of the Ear and Throat Hospital, the Women's Hospital, and the Skin Hospital. The expenses of each of these hospitals have been considerably increased in consequence of building extension which has been undertaken to relieve the great pressure upon the accommodation. The Women's Hospital is in process of being rebuilt on a new site and is expected to be ready for opening some time during the summer. The extension in connexion with the Skin Hospital had largely for its end the better equipment of the operating theatre and the Roentgen ray and Finsen light departments. Great as the pressure is upon the hospitals it would be still greater were it not for such institutions as the Hockley Provident Dispensary—the annual report of which has just been issued—which is self-supporting, it being founded on the principles of self-help, and where the members can obtain medical attention in times of sickness. A complaint alluded to in all the annual reports—a complaint, moreover, which is rapidly becoming a grievance—is that the Birmingham charities are largely used by patients who live outside the area of Birmingham and its suburbs and that from these outlying districts there is no commensurate contribution. In the report of the Ear and Throat Hospital it was stated that 31·7 per cent of the in-patients and 26·1 per cent. of the out-patients were from beyond Birmingham. The city in the past has not suffered from the lack of charitable bequests nor have the working classes been behind in contributing, since in addition to maintaining their own convalescent homes in North Wales they have for several years handed over an annual sum of £10,000 to the various hospitals. It is extremely rare, on the other hand, for the hospitals to receive any contribution from the outlying districts the poor inhabitants of which benefit so largely by them.

The Housing Committee and the Bordesley Green Site.

Some time ago the housing committee, under Part 3 of the Housing of the Working Classes Act, purchased 17 acres of land at Bordesley Green with the view of building houses for the working classes. The committee later considered it inadvisable to build the houses and determined to let the land to a private builder. An offer has recently been made by a builder who covenants to build upon the site not less than 310 and not more than 340 houses. Each house will consist of a living room, a kitchen, and two bedrooms, one of which can be divided if necessary into two, and there will be a water-closet attached. There will be an area in the centre of the site unbuilt upon for the use and recreation of the residents. Not less than two-thirds of the houses are to be let at 4*s.* 6*d.* a week and the rest at 5*s.* The builder agrees to pay a ground rent of £400 a year and to take the land on a 99 years' lease. The whole scheme will be laid before the council at its next monthly meeting.

Mentally and Physically Defective Children.

Mentally and physically defective children formed the subject of an interesting address given at the University a few days ago by Mrs. Hume Pinsent who is a member of the Royal Commission now sitting to consider the education of these children. She particularly emphasised the fact that they were weak in will power and strongly imitative and that, in consequence, if taken from evil surroundings, placed under supervision, and given manual work there was every reason to hope that they would be self-supporting. To effect this result boarding schools were necessary, for in day schools only during school hours were the children protected from evil communications. It was necessary, further, that provision for the education and protection of such children should be compulsory, otherwise there was the absurdity of one township spending money upon them, only to see them at the end of a year removed to a district where such provision was not operative and where they would speedily lose all the advantages which they were in process of gaining. The final problem was to render them when they were grown up self-supporting and to prevent them from aggravating the evil by becoming the parents of a new generation similarly defective. This it was proposed to solve by the institution of colonies where they could work under constant supervision. The large audience which listened to the address showed the interest which many in Birmingham take in the question and gave reason for hope that some serious endeavour would shortly be made to grapple with the subject.

Worcestershire and the Treatment of Consumption.

The annual meeting of the Worcestershire Association for the Prevention of Consumption was held a week ago. The general committee, reporting upon the work done during the year at the sanatorium for the open-air treatment of the disease at Knightwick, was able to make the gratifying statement that in 87 per cent. of the cases in the early stages of the disease the mischief was arrested. So satisfactory were the results considered that the committee recommended the purchase of a site and buildings at a cost of £6000, of which some £2000 have already been promised although no general appeal has yet been made.

The City Analyst's Report.

From the report by the city analyst to the health committee it is found that the adulteration of food is on the decline. Of the samples analysed last year only 5·3 per cent. were adulterated in other ways than by preservatives. Of the samples of milk examined 4·7 per cent. were adulterated with preservatives only and 6·5 per cent. by the addition of water or the abstraction of fat. These figures are lower than those of any previous year. Preservatives were detected in 37 samples of milk, 12 containing borax or boric acid and 25 containing formic aldehyde. Of the samples of butter 5 per cent. were adulterated in other ways than by preservatives. Perhaps the most interesting information referred to the examination of the water. Samples taken from taps from January to October were of the old supply and contained from 26·6 to 36·8 parts of solid matter per 100,000 parts of water; samples taken in November and December were of the new Welsh supply and contained only 8 parts of solid matter in the same volume of water. The amount of hardness had also decreased from 20 parts to 3·5, and whereas the old supply always contained nitrogen as nitrates the new supply is quite free from such suspicious constituents.

Local Bequests.

By the will of Mr. Richard Cadbury the Birmingham General Hospital and the Eye Hospital have each benefited to the extent of £5000, while the Ear and Throat Hospital and the Orthopædic Hospital have each received £2500.—Sir Edward Dolman Scott has bequeathed to the Staffordshire General Infirmary and to the Queen's Hospital, Birmingham, £5000 each.—The residuary interest in his estate which Mr. Best, after directly benefiting certain charities, left to the general purposes committee of the council to be disposed of as it thought fit amounted to £70,000. This sum has now been allocated and in consequence the University receives £20,000, the Birmingham and Midland Institute £3000, and the General and Queen's Hospitals £5000 each.

The Health of Birmingham.

For the week ending March 18th the death-rate was 15·9 per 1000, the zymotic death-rate being 1·2. During that week two fresh cases of small-pox were notified; there were five cases in the special wards at the end of the week. For the week ending March 25th the death-rate was 14·3 per 1000, the zymotic death-rate being 1·1. There was one fresh case of small-pox notified during the week.

April 4th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

University of Liverpool: Graduation Ceremony.

AN interesting ceremony took place at the University on April 1st when the degrees of Bachelor of Medicine and Bachelor of Surgery were conferred by Vice-Chancellor Dale upon Mr. J. A. M. Bligh, Mr. D. Elder, Mr. W. D. Higson, Mr. E. F. Hoare, Mr. L. Hutchinson, Mr. J. S. Rowlands, Mr. J. C. Thorburn, Mr. H. W. L. Waller, and Mr. H. F. Woolfenden. The ceremony was witnessed in the Senate room by a number of the graduates' relatives and friends. The candidates were introduced to the Vice-Chancellor by Professor B Moore, the Dean of the Medical Faculty. In an address to the new graduates the Vice-Chancellor reminded them of the Old Students' Association and of the invaluable services which it had rendered to their corporate life.

Infirmary for Children and the Finance Committee of the City Council.

I understand that a deputation from the committee of the Liverpool Infirmary for Children recently waited upon the finance committee of the city council for the purpose of advising the council to grant a sum of money towards the completion of the new hospital, for which there is urgent need. The finance committee could not see its way to accede to the request of the deputation. The supporters of two other Liverpool hospitals at their recent annual meetings have advocated corporate help but so far as I know there is no precedent for such an expenditure.

The Liverpool Medical Institution.

A special general meeting of the Liverpool Medical Institution was held on March 23rd to consider proposals made by the council of the society for enlarging the accommodation by the absorption of the resident librarian's house adjoining the building and for the provision of greater facilities for members and associates. The structural alterations will involve an estimated expenditure of £1700, only a third of which can be safely met by funds at the treasurer's disposal. The meeting sanctioned the proposals of the council in so far as the necessary alterations were concerned but adjourned the consideration of the financial proposals to a future special general meeting.

The Midwives Act, 1902: Registration in Liverpool.

The Midwives Act, 1902, which came into operation on April 1st, makes the registration of midwives compulsory and to be entitled to registration women must either hold [illegible] been in the discharge of the [illegible] previously to July, 1902. Dr. [illegible] of health of Liverpool, has charge of the registration in Liverpool and of the enforcement of the rules which have been made by the Central Midwives Board and approved by the Privy Council. Already a large number of midwives have registered in Liverpool. The city is well supplied with qualified midwives. 70 per cent. have been trained at the Liverpool Lying-in Hospital, whilst others hold certificates from the Obstetrical Society of London. The supervising authority has power to inspect every midwife's case-book, appliances, &c., and, where thought necessary, her place of residence, the object in view being to prevent the spread of puerperal fever.

The Skeleton of Ambush II.

The skeleton of Ambush II., the famous race-horse which carried His Majesty's colours to victory in the Grand National steeplechase of 1900, recently presented by King Edward to the University of Liverpool, has just been mounted on an ebony base. The skeleton at present occupies a temporary position in the centre of the dissecting room of the veterinary school where every detail can be readily seen.

St. Paul's Eye Hospital: Recognition by the University of Liverpool.

AT the recent annual meeting of the supporters of the above charity it was announced that the hospital is now recognised by the Royal Colleges in London and that it forms an integral part of [illegible] connexion with the [illegible] has not yet been able to procure a site on which to erect a new hospital. The managers have approached the corporation several times with reference to certain plots of land but have been unable so far to arrive at an arrangement.

April 4th

LEEDS.

(FROM OUR OWN CORRESPONDENT.)

The Water-supply of Leeds.

THE rapid growth of the city of Leeds has necessitated certain developments and extensions in connexion with its water-supply, some of which will be immediately commenced. The subject of the "Leeds Waterworks, Old and New" was dealt with in a most interesting manner by Mr. Councillor Armitage, the chairman of the waterworks committee, in a lecture which he delivered before the Leeds branch of the Society for the National Registration of Plumbers. The earliest mention of waterworks in connexion with Leeds was of the date of 1694, when a company was formed for pumping water from the river Aire at a position close to Leeds Bridge. 60 years afterwards this supply was increased and in 1790 the first Act of Parliament was applied for and this Act, amended by another in 1809, was concerned purely with the water from the Aire. In 1837 another Act was applied for as the water of the Aire had become unfit for use. That Act was to impound the water and springs at Adel, Allwoodley, and Harewood in a reservoir at Woodhouse Moor. In 1847 the company obtained powers to pump 2,500,000 gallons per day out of the Wharfe at Arthington. In 1852 the corporation purchased the undertaking from the company for £225,000. In 1862 the amount allowed to be pumped out of the Wharfe was increased to 6,000,000 gallons per day. In 1867 the great Washburn valley scheme was entered upon. Three reservoirs were constructed at Fewston, Swinsty, and Lindley respectively, the last being used as a compensation reservoir. The scheme was finished in 1869 and it was decided to construct the reservoir at Eccup to take the overflow water. The Washburn area was ten and a half miles long and six miles broad. Mr. Armitage then gave an interesting account of the steps taken by the corporation to open out new areas of supply. Extra ground had been secured in the Washburn area to increase the supply and to insure purity, but it was clear that some large scheme was necessary and the Ure valley scheme had been decided upon. The estimated cost of the Ure valley scheme is £2,200,000, including pipe laying. The plans show four reservoirs—viz., those at Colsterdale, Leighton, Carlesmoor, and Laverton—with a capacity of 4,543,000,000 gallons and a daily yield of 15,500,000 gallons. The Colsterdale reservoir will be the largest of the series; it will cover an area of 170 acres and its capacity will be 1,852,000,000 gallons. The daily yield to Leeds will be 7,296,000 gallons and the compensation water will be 3,648,000 gallons. The structure of the embankment was fully discussed by the lecturer. This will be 110 feet in height and will involve the putting together of some 800,000 cubic yards of earth. During the winter months a great deal of discussion went on in the local press and at numerous meetings as to whether on humanitarian as well as economic grounds the work should be done by the corporation which would thus be able to afford employment to those out of work. The matter was fully considered by the corporation which, very wisely as I think, decided that the work should be done by contract. Among the unemployed there may, indeed, be some with the physical strength required for the work of a navvy but as the result of a natural system of selection it is the least skilled and the weakest physically who swell the ranks of the unemployed and certainly the unemployed of a large city are quite unfit for laborious work of this kind. Subject to the approval of the corporation the waterworks committee has accepted the tender of Messrs. R. McAlpine and Co. of Glasgow for the Colsterdale reservoir, which is £297,000. Some conditions attach, however, to the making of the trench. The nature and the direction of the strata it appears are open to doubt, and should these factors prove unfavourable the cost to the corporation may amount to £500,000. The committee has also recommended the appointment of Mr. Henzell, M.I.C.E., as waterworks engineer to the city at a salary of £1000 with staff and office. Accommodation has been provided for about 1000 navvies in the form of a village of huts, with water-supply and drainage system, isolation hospital, surgical hospital, mission room, canteen, and recreation rooms. The corporation is also going to try the experiment of tree-planting in the Washburn valley and a barrack is being erected for the accommodation of about 50 men who will be recruited mainly from the class of the unemployed.

March 4th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Direct Representation for Ireland on the General Medical Council.

Dr. Leonard Kidd of Enniskillen has announced that he will be a candidate for the representation of the medical practitioners of Ireland at the election for the General Medical Council in January, 1906, Dr. Kidd holding that the Direct Representative should be a general practitioner. Sir William Thomson has addressed a circular letter to the registered medical practitioners of Ireland referring to the work which he has already done for them on the committees of the Council and to the fact that the Direct Representatives are intended to be the protectors, not of any class in the profession, but of the whole body of the profession as distinguished from the representatives of university and licensing corporations. [illegible] from anything personal towards the candi-[illegible] both in Dublin and in [illegible] me has come when a [illegible] ld get a seat on the Council. In Ireland at present there are 2632 medical practitioners and there are seven representatives on the General Medical Council from that country, one each from the Royal College of Physicians, the Royal College of Surgeons, the Apothecaries' Hall, the University of Dublin, and the Royal University of Ireland, one Crown appointment, and one Direct Representative, every one of whom resides within the four walls of Dublin. England and Wales, with 24,351 practitioners, have 17 representatives on the Council and of these only seven reside in London, while ten come from the provinces; Scotland, with 3733 practitioners, has nine representatives, of whom three come from Edinburgh and six from other parts of that country. Surely, following the analogy of England and Scotland, it is hardly fair that in Ireland every representative on the Council should be a Dublin man and that the provincial districts should be without representation.

Fatality from Burns in Dublin.

It has been stated many times that the high mortality in Dublin is largely due to the death of infants. The President of the Royal College of Physicians recently emphasised the fact. Mr. Louis A. Byrne, the city coroner, has just written to the public health committee on the subject, his letter being addressed to Sir Charles Cameron. It is long and contains some important statements. For instance, the number of deaths from burns in 1903 amounted to 39, in the year 1904 to 32, and for the month of January and February in this year 12. The number of burns and scalds treated at Jervis-street Hospital from July 1st, 1904, to March 1st, 1905, was 83. The coroner remarks that this is but a very small proportion of those who have been received in the city hospitals generally. He concludes his letter by strongly recommending the use of a simple and inexpensive screen which should be placed in front of fires in houses containing infants and young children.

Irish Medical Politics.

If perfect contentment with things as they are and a belief that this is "the best of best worlds" indicate a state of stagnation in any body or society it certainly does not exist in the medical profession in Ireland at the present time, for never were there such free expression of opinion and such diversity of views. The Irish Medical Association is in a state of ferment over the report of Surgeon-General G. J. H. Evatt and the last number of the journal of that society shows how wide a cleavage there is in that body, and it is expected that when the members meet at their annual conference on June 7th in Killarney there will be a lively and animated discussion. Even among those most opposed to Surgeon-General Evatt's report there is a unanimity that a reconstruction of the executive of that association is required. Then the Leinster branch of the British Medical Association is at this juncture moving for the formation of an Irish committee which shall report to the central council on any matters specially concerning Ireland; and finally, as indicated above, we have looming in the future an interesting contest for the direct representation of the profession on the General Medical Council, in which the provincial general practitioners will apparently make an effort for representation. All these facts indicate that a remarkable awakening is setting in among the members of the medical profession in Ireland.

The Royal University of Ireland.

The election of six representatives on the Senate of the Royal University of Ireland will take place next month. There are two medical candidates, Dr. J. Walton Browne and Dr. R. W. Leslie who has been nominated as a candidate in place of Professor T. Sinclair (who does not wish re-election) by the Royal University Graduates' Association.

Ulster Hospital for Women and Children, Belfast.

At the annual meeting of the supporters of this hospital held on March 21st it was reported that 261 cases were admitted into the children's wards during the past year, while there were 2261 out-patients, of whom 488 were ophthalmic cases. 82 cases were admitted into the women's wards and there were 553 extern gynæcological cases. 11 women were admitted into the maternity ward and 161 were attended at their homes. The total number of cases afforded relief by the hospital during the year was 3320, an increase of 23 per cent. over the year 1903. The total income was £705 17*s.* 11*d.* and the total expenditure was £950 14*s.*, showing a deficit of £244 16*s.* 1*d.*, equal to about £25 per month. This deficit was met by drawing upon the balance of the Ulidia bazaar proceeds.

The Mater Infirmorum Hospital, Belfast.

From the twenty-first annual report of this hospital for the year ending Oct. 31st, 1904, it appears that there were 1563 intern patients, 2204 accident cases, 345 surgical operations, and 21,900 cases treated in the dispensary. The expenditure for the past year was £5178 13*s.*, leaving a balance due to the bank of £125 7*s.* 5*d.* Additional funds are urgently needed for the ordinary outlay of the hospital and for the development of the convalescent home.

Belfast Ophthalmic Institution.

At the annual meeting of the supporters of this institution held on March 22nd it was stated in the medical report that 2219 extern and 159 intern cases had been treated during the past year. The operations numbered 100. Financially there is a balance due to the bank of £96 5*s.* 7*d.* It is to be regretted that a sum of £50 appealed for in the last report for the proper furnishing of the operating theatre has not been forthcoming. The honorary secretary has again offered that provided the committee raises £100 during the year he will give £50 for pressing alterations in the hospital. During the last four years £440 have been spent in necessary improvements and changes in the building.

Health of Belfast.

At the monthly meeting of the city corporation held on April 3rd it was reported that for the past six weeks there had been no fresh cases of small-pox and that for the past month the death-rate had been 23·8 per 1000. Scarlet fever and simple continued fever are less prevalent, as well as diphtheria and erysipelas, whilst cases of enteric fever are on the increase. The corporation rescinded a by-law passed by the markets committee that "all meat killed outside the city and brought into the city for sale shall, before being sold or exposed for sale, be brought, together with the head, heart, lungs, pleura, liver, spleen, kidneys, intestines, and peritoneum of the same beast, into the market appointed by the council for inspection by one of their inspectors of provisions between the hours of 8 A.M. and 10 A.M., and shall not be sold or exposed for sale until after same has been inspected and passed by him as fit for human food." The council also decided to complete the works for the drainage of the asylum and infectious diseases hospital at Purdysburn, a plan which necessitates the sewage being brought through the city and which has been much objected to by the inhabitants.

April 4th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Thyroid Grafting.

AT the meeting of the Academy of Medicine held on March 21st M. Lannelongue read, on behalf of M. Gauthier and M. Kummer, a communication relative to a child, aged three years, on whom they had grafted a fragment of thyroid gland taken from a girl afflicted with goitre. The case was interesting as regards cretinism and its modern treatment. Cretinism is due to functional insufficiency of the thyroid gland and both cretins and myxœdematous patients have been successfully treated by giving them the thyroid gland of animals by the mouth. Other observers have thought it better to graft a piece of thyroid gland under the skin and if the graft "takes" it grows and assumes the functions of the normal gland. In the same way ovarian tissue has been grafted on women whose ovaries had been removed and who suffered from disturbances owing to the absence of these structures. M. Lannelongue tried thyroid grafting for the first time in 1890, the graft being taken from a sheep. Later other observers tried the treatment and Christiani of Geneva showed that a graft from a human being was most likely to meet with success. In the case under the care of M. Gauthier and M. Kummer the graft "took" successfully and ten months after the operation the myxœdematous condition of the patient was much improved.

The Purification of Drinking Waters.

The city of Paris is about to open a competition for the ascertaining of the best method applicable to a town supply of purifying water for drinking purposes. Those desirous of competing must send to the Prefecture of the Seine all documents, such as specifications, memoranda, and the like, which will give a complete explanation of the system in question, the results which may be expected from its adoption, the expense of installing the plant, and its method of working for the supply of a definite quantity. Prizes are to be allotted which will vary in amount between 1000 francs and 3000 francs, the total sum to be given in prizes not to exceed 6000 francs.

Trephining for Fracture of the Skull.

At the meeting of the Surgical Society held on March 22nd M. Demoulin read a paper for M. Lenormand concerning the case of a man, aged 35 years, on whom the latter had operated for the following conditions. The patient received a violent blow from a bar on the right temporo-parietal region. He received a first dressing and was able to walk for a distance of 200 metres. During the night he vomited and the following morning he was taken to the hospital. On being examined 36 hours after the accident he was found to have an enormous hæmatoma of the injured region, with depression of the bone, a raised temperature, some incoördination of the movements of the left arm, and explosive phonation (*bredouillement de la parole*). Operation was decided upon, the blood clot was removed, and the underlying bone was found broken into fragments which were removed. There was no blood within the skull but the dura mater was torn for about four centimetres. This was sutured and the external wound was drained. Next day the facial paralysis had disappeared and a few days later the patient was well. Despite the favourable outcome of this case M. Demoulin considered that in view of possible infection of the tissues underlying the dura mater it would have been preferable to enlarge the opening in that membrane and to examine the arachnoid cavity. The dura mater should then have been partly sutured, a small drain being left in. This course M. Demoulin proposed to follow in a similar case.

Demonstrations by Medical Students.

The medical students of Paris considering themselves aggrieved by the severity of M. Gariel, professor of physics, in his capacity of examiner, organised demonstrations against him, both during his lectures and outside his house. The police were called in and the chief of the municipal police struck a student with a cane. This incident gave rise to great excitement in the Quartier Latin and on, March 20th 1500 students demanded the dismissal of the chief of the municipal police. That official appealed to the prefect of police, M. Lepine, who in the presence of the students blamed the action of the chief of the municipal police and promised to send to the corporate association of the students of medicine a letter putting this opinion on record, which letter was sent directly on M. Lepine's return to the prefecture. The students dispersed but M. Debove, dean of the faculty of medicine, has suspended M Gariel for the time being from lecturing.

April 3rd.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

Annual Report of the Montreal General Hospital.

THE eighty-second annual meeting of the corporation and board of governors of the Montreal General Hospital took place during the last week of February, when it was announced that the annual income for 1904 had fallen off to the extent of $7605, which has caused the board of management no little anxiety. The income for 1904 amounted to $83,589 and the expenditure to $95,508.88. The board of management expressed the hope that the citizens of Montreal would come to its aid, so that there would be no necessity to limit the number of patients per month in the institution, as the board of management had to do in 1869, with a deficit of half of the present shortage. During the past year $25,000 have been added to the endowment fund, which brings the total amount of that fund up to $75,000. Dr. F. G. Finley, the secretary, presented the annual medical report, which showed that the total number of patients passed through the wards was 3144 as [illegible] emained in the hospital 201 at [illegible] scharged during the year numb [illegible] deaths. The percentage of mortality was 7·98, or 4·9 exclusive of deaths occurring within three days of admission. The average number per diem in the wards was 189·1 and the average number of days spent in the wards by each patient was 22·05. The aggregate [illegible] patients in the hospital [illegible] patient daily was $1.3[illegible] In the outdoor departments there were 1973 males and 1171 females treated and 38,922 consultations. The ambulance responded to 1511 calls. Dr. Finlay was re-elected secretary. The staff elected for the ensuing year was as follows:—Physicians: Dr. W. A. Molson, Dr. A. D. Blackader, Dr. Finley, and Dr. H. A. Lafleur. Surgeons: Dr. F. J Shepherd, Dr. George E. Armstrong, Dr. J. A. Hutchison, and Dr. J. M. Elder. Assistant physicians: Dr. F. W. Campbell, Dr. G. Gordon Campbell, and Dr. S. Ridley McKenzie. Assistant surgeons: Dr. Kenneth Cameron, Dr. Charles W. Wilson, and Dr. J. Anderson Springle. Specialists: diseases of the eye and ear, Dr. John J. Gardner. Assistant in diseases of the eye and ear, Dr. J. W. Stirling. Gynæcologist: Dr. F. A. L. Lockhart. Assistant gynæcologist: Dr. John D. Cameron. Laryngologist: Dr. D. H. Hamilton. Assistant laryngologist: Dr. George K. Grimmer. Neurologist: Dr. David A. Shirres.

Tuberculosis discussed in the Canadian House of Commons.

A motion was a short time ago presented to the Canadian House of Commons by one of the hon. members thereof, the substance of which was to the effect that the time was opportune when the Canadian Government should materially assist in the work of checking the ravages of the "great white plague." The motion met with the hearty and unanimous sympathy of the entire House and will be sure to do a great deal of good in fighting this disease. One good outcome of the resolution will be that it is not alto- [illegible] will appoint a Royal [illegible] t of tuberculosis in [illegible] bt, also be empowered to make representations as to the best means of combating the spread of the disease. The annual meeting of the Canadian Association for the Prevention of Tuberculosis took place at Ottawa, when Professor J. George Adami of McGill University, Montreal, [illegible] to the Fellowship of the Ro[illegible] ress on Adaptation in Consumption.

Canadian Medical Men and North-West Autonomy.

The Prime Minister, Sir Wilfrid Laurier, has introduced a Bill into the Federal House of Commons to provide for the creation of two provinces out of what have heretofore been denominated the North-West Territories; and as a result some of the medical profession in the other provinces of Canada feel exercised as to whether the matter of registration to practise there is going to be left in the hands of the respective new legislatures. In fact, some of the local medical societies of Canada have had the matter under discussion and in certain quarters there prevails the opinion that the question of registration in the two new provinces should, for a few years at any rate, be left open, so that those practitioners who are registered in the older provinces could have a chance to register there should they so desire. The argument has been advanced that as the Government of Canada purchased this vast country from the Hudson's Bay Company the physicians of Canada, those of the older provinces which then constituted the Dominion of Canada, have a right in it as well as those of the balance of the community. The *Dominion Medical Monthly*, which circulates largely throughout Manitoba, the Territories, and the West, advises that the medical men of the two new provinces have the right to legislate as they see fit until such times as Dominion registration becomes the medical law of Canada.

Amalgamation of McGill Medical Faculty and Bishop's Medical College.

Following the example set by the medical faculty of the University of Toronto and the medical faculty of Trinity University, Toronto, McGill medical faculty and the medical faculty of Bishop's College University of Montreal are talking of amalgamation and there appears to be every likelihood that the amalgamation will take place. Meetings of representatives of the two faculties have been held but nothing has been given out for publication of a tangible character. Consolidation, however, is not far off. McGill University probably feels that it must do something to keep pace with its great rival Toronto. Now, of course, in the matter of students the University of Toronto leads by many and is continuously gathering in students from quarters which a few years ago were looked upon as McGill University's special preserves. The union is a desirable one.

Toronto, March 9th

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Council on Pharmacy and Chemistry.

THE American Medical Association has, as I said in my letter a fortnight ago, established a Council of Pharmacy and Chemistry the purpose of which is to examine into the composition and status of the various medicinal preparations which are offered to physicians and which are not included in the United States Pharmacopœia or in other standard text-books or formularies. These preparations will include the synthetic chemical compounds as well as the so-called proprietaries and pharmaceutical compounds put out under trade-mark names. Rules governing the matter have been established and preparations which conform to the standard fixed by the rules will be incorporated in a book entitled "New and Non-official Remedies" and issued by the American Medical Association. The acceptance of an article will be based on a careful and unprejudiced examination of the accessible information from all sources and in compliance with the adopted rules. An acceptance is not to be interpreted as an endorsement, neither is omission from the list to be construed in every case as condemning an article, for it may mean that the necessary information has not been obtained. The council does not pass judgment on the therapeutic value but on the ethical status only; neither does it presume to dictate what preparations shall be prescribed but supplies necessary and desirable information concerning those which it considers unobjectionable. The council believes that there are many articles at present not recognised by the Pharmacopœia which comply with the required standard and do not need any farther investigation. Some of the more important rules adopted by the council are as follows:—

1. No article will be admitted unless its active medicinal ingredients and the amount of such ingredients in a given quantity of the article are furnished for publication.

2. Information must be furnished as to tests for identity, purity, and strength, and if a synthetic compound the rational formula.

3. No article that is advertised to the public will be admitted except [illegible] mineral waters. [illegible] whose label, package, or circular [illegible] he treatment of which the article is indicated.

There are ten rules of this kind. The members comprise the leading pharmacists of the country.

Tent Treatment for Consumption.

The Hudson County (New Jersey) board of freeholders, according to the New York *Sun*, has decided to establish a hospital for pauper tuberculous patients. Large tents will be used and the out-of-door treatment will be followed as closely as possible. The county authorities have had their attention called to the necessity of separating consumptives from the other inmates of the almshouse. It was at first proposed to establish a trolley car colony for those suffering from pulmonary tuberculosis and the president of the public service corporation offered to place a quantity of abandoned trolley cars at the disposal of the almshouse authorities. They, however, concluded that the tents would be cheaper and more serviceable than the old cars.

Sanatorium for Inoperable Cancer.

A sanatorium at Fairhaven, near New York, for the treatment of cases of inoperable cancer will soon be incorporated. The need of such an institution is testified to by all New York physicians and the only obstacle standing in the way is lack of funds for its first year. The Fairhaven sanatorium will be used solely for inoperable cases which are not admitted to the wards of general hospitals. The medical profession is particularly anxious that an institution of this nature should be established, for the reason that it would afford an opportunity for an exhaustive study of the disease. A medical board has been decided upon to aid in the management of the institution, consisting, among others, of Dr. William B. Coley, Dr. B. F. Curtis, Dr. George F. Shrady, Dr. Austin Flint, jun., Dr. A. Blake, and Dr. Edward B. Cragin.

Yellow Fever on the Isthmus of Panama.

Yellow fever is somewhat prevalent on the Isthmus of Panama and in consequence of this fact General Davis, Governor of the Panama Canal zone, has notified the Secretary of War that he can dispense with nearly all the marines on the isthmus. Accordingly the Secretary of the Navy has been called upon to order all the marines north except about 100.

Cerebro-spinal Meningitis in New York and Philadelphia and in other American Towns.

Cerebro-spinal meningitis has been remarkably prevalent in New York during the past few weeks. In Philadelphia, too, there has been a large number of cases of the same disease. The last great epidemic of this malady in New York up to this year took place in 1872. From Jan. 1st to Nov. 1st at that time there were reported to the health department a total of 990 cases, of which 761, or nearly 77 per cent., proved fatal. During February of this year 149 deaths occurred in this city from cerebro-spinal meningitis and the disease shows little signs of abating. Dr. Craig of Philadelphia was recently attacked by the disease and died before he could be isolated. On March 18th cerebro-spinal meningitis was discovered in the Philadelphia Hospital and Almshouse and the greater part of that institution has been placed under strict quarantine. So serious is the situation thought to be in New York that an appropriation has been made by the city board of estimate to allow for the appointment of a commission to investigate and to endeavour to discover a preventive of cerebro-spinal meningitis. Dr. Darlington, president of the New York health department, has appointed the following commission: Dr. William Polk, chairman, dean of Cowell Medical College; Dr. Walter B. James, professor in the New York College of Physicians and Surgeons; Dr. William P. Northrup, professor in children's diseases in Bellevue Hospital and at the University of New York; Dr. Simon Flexner, head of the Rockefeller Institute; Dr. Joshua M. van Cott, pathologist at the Long Island College; Dr. E. K. Dunham, pathologist of Carnegie Laboratory; and Dr. William K. Draper, visiting physician at the Bellevue and Minturn Hospitals. The commission will not undertake any active work but physicians who have cases of cerebro-spinal meningitis will be requested to make experiments and tests and send them to the commission, the members of which will consider them and endeavour to devise means of preventing the disease or of alleviating its spread. As in other epidemics most of the victims are children, especially those from one to five years of age, and the majority of them are drawn from the lower classes. Cerebro-spinal meningitis is supposed by some to follow severe winters but the history of the disease does not altogether bear out this view. In Yonkers, a town situated about 20 miles from New York, 39 deaths from the disease have occurred since the blizzard of Jan. 25th.

March 27th.

Medical News.

VICTORIA UNIVERSITY OF MANCHESTER.—Degrees were conferred upon the following candidates in March:—

Bachelor of Medicine and Bachelor of Surgery (M.B., Ch.B.).—George Duncan Dawson*, Eric Maurice Wilkins*, Frank Leigh Boag, Archibald Cambell, Catherine Louisa Corbett, Joshua Bower Dalton, Ronald Leslie Ferguson, Henry Edward Tox, Wilson Harold Hey, Richard Woodward Higson, Ernest Hulme, Thomas William Lonsdale, George Gray Parkin, James Smalley, Henry Thorp, David Walker, and John Stirling Young.

* Second-class honours.

UNIVERSITY OF LEEDS.—The following candidates have passed in the several examinations which have just been held:—

Second M.B., Ch.B.—W. L. Dibb and W. D. Hamilton.

Final M.B., Ch.B.—Part I.: E. R. Flint, F. E. Kendall, and W. O. McKane. Part II.: F. Bailey, C. N. Smith, A. B. S. Todd, and M. G. L. Walker.

In conferring the degrees on those who had passed Part II. the Vice-Chancellor remarked on the appropriateness of the first degrees in the University, other than honorary degrees, being conferred in medicine and in the buildings of the medical school, which was the oldest department of the University.

UNIVERSITY OF GLASGOW.—The following have passed the first professional examination for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.) in the subjects indicated (B., Botany; Z., Zoology; P., Physics; and C., Chemistry):—

David Rutherford A[illegible] *P.,* C.*), Andrew Clark Anderson (Z[illegible] (Z., C.), William Anderson (Z., C.) [illegible]nstrong (P., C.), James Currie A[illegible] (Z., C.), Arthur Munby Bayne (Z[illegible] Beard (B., Z.), Charles Stewart [illegible] P., C.), Douglas Morris Borland (Z.), Charles Brash (B., P.), Morris William Broudy (B., Z., P., C.*), Alexander Hogg Brown (B., Z., C.), Carl Joseph Barrett Buchheim (B., Z.), John Adam Gib Burton (Z., P., C.), John Allan Munro Cameron (Z.,* P.*), Andrew Hood Clark (Z., C.), James [illegible] Cook Coalburn (B., Z.), Rutherford [illegible] B., Z.), Charles Duguid (Z.,* C.), Don[illegible] Scoular Fleming (Z.), George Fletcher, M.A. (Z., C.), Robert Dunlop Black Frew (P., C.), James Brunton [illegible] (Z.), William Ernest Gemmell (Z.), Da[illegible]), Robert I[illegible]),

Women —Rose Isobel Hudson (M), Edith Oversby (P., M). Agnes Picken, M A (P, M *), Margaret Baillie Taylor (M), and Christina Gibson Thomlinson (P.)

Robert Stewart M'Kim, M A., has passed the third professional examination (regional anatomy, materia medica and pharmacy, and pathology*) for the degrees of Bachelor of Medicine and Master in Surgery (M B, C M).

* Passed with distinction in the subjects indicated.

TRINITY COLLEGE, DUBLIN.—At examinations for the diploma in public health held in Hilary term the following candidates were successful:—

Part I —Robert J. Fleming and Douglas S B Thomson.

Part II —Thomas P. Griffin and Douglas S. B Thomson

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Professor Rudolf Renvers, Director of the Medical Department of the Moabit Hospital and surgeon-general in the Prussian army, has been ennobled. Dr. Renvers attended the late Empress Frederick for many years. The following *privat-docenten* have been granted the title of Professor: Dr. Ferdinand Blumenthal, assistant to Professor Leyden in the First Medical Clinic, Dr de la Camp, assistant in the Second Medical Clinic; Dr. Adolf Magnus Levy, formerly assistant to Professor Naunyn in the Strasburg Medical Clinic; and Dr Walter Stoeckel, who has charge of the Gynæcological Institute of the Charité under Professor Bumm.—*Brussels:* Dr. Gallemaerts has been appointed Professor of Ophthalmology and Director of the Eye Clinic.—*Budapest:* Dr S. Beck has been recognised as *privat-docent* of the Dermatology of Children.—*Cologne (Academy of Practical Medicine):* The chair of Pathological Anatomy has been offered to, and accepted by, Dr Leonhard Jores of Brunswick.—*Florence:* Dr. A. Perassi of Turin has been recognised as *privat-docent* of Surgery and Operative Medicine.—*Heidelberg:* Dr Peckert has been recognised as *privat-docent* of Odontology.—*Munich:* Dr Erich Meyer has been recognised as *privat-docent* of Internal Medicine.—*Naples:* Dr. Antonio Iovane has been recognised as *privat-docent* of Pædiatry.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following is the list of prizes awarded for the winter session, 1904-05.—Descriptive Anatomy: Junior. G. C. Sneyd, first
and R. Adams, second prize (£1) and
H. W. White, first prize (£2), and
y, second prize (£1) and certificate.
y: First year. Miss I. M. Clarke, first
edal, and C Greer, second prize (£1) and
nd year: G. S. Levis, first prize (£2) and
ey, second prize (£1) and certificate.
Lucas, first prize (£2) and medal;

and G. M. Loughnan, second
Physiology: A. E. S. Martin, first
G. S Levis, second prize (£1)
R. H. F. Taaffe, first prize (£2)
and Miss I. M. Clarke (equal),
Pathology: G. F.
and C. J. Hare, second
R. Adams, first prize

(£2) and medal; and Miss I. M. Clarke, second prize (£1) and certificate.—The lectures and practical courses of the summer session commenced on Monday, April 3rd.

The congratulatory dinner to Dr. C. Owen Fowler, who was recently acquitted of foul and baseless charges brought against him in the divorce court, will be held on Thursday, May 4th, at 8 o'clock, at the Greyhound Hotel, Croydon. Tickets, exclusive of wine, 5*s.* each, may be obtained from Mr. C. M. Fegen at the Town Hall, Croydon.

Royal Infirmary, Leeds.—The governors of this institution have, on the recommendation of the board, passed rules to prevent any honorary officer appointed under the 1884 rules from holding office beyond the age of 65 years and to prevent any honorary officer to be hereafter made a member of the staff from holding office beyond the age of 60 years, the 20 years' limit of service being also retained. The board also recommended that every honorary assistant physician or surgeon should be obliged to retire after ten years' service and to submit himself for election as honorary physician or surgeon with charge of out-patients and that the succession of the honorary physician or surgeon with charge of out-patients to the post of full physician or surgeon should be by seniority only and that honorary assistant physicians or surgeons should, after five years' service, automatically succeed to the charge of a limited number of beds in the infirmary. It may be pointed out that when a member of the full honorary staff has completed his term of office—that is to say, a term of 20 years—or in the case of anyone who may be elected in the future either a term of 20 years or such term until he attains the age of 60 years, he retains as honorary consulting physician or surgeon the right to the use of six beds.

New Hospital for Skin Diseases, Manchester.—The new building for the Manchester and Salford Hospital for Skin Diseases in Quay-street is now nearly completed. The site is adjoining the old hospital at the corner of Byrom-street and Quay-street. It has only been possible to proceed with about two-thirds of the new hospital at present, i.e., the central administrative block and the right wing, with wards, yards, and large waiting rooms for out-patients. When the new buildings are ready for occupation the old house will be pulled down and on its site the left wing will be built. The new hospital will contain 28 beds and the out-patients' room will seat 200 patients. There will be an operating theatre and mortuary and the usual appliances of a hospital. It is estimated that the total cost will be more than £38,000, of which £32,000 have been raised. Manchester soon followed London in the use of Finsen's treatment. The Queen, when Princess of Wales, presented the first set of Finsen's instruments to the London Hospital and takes, as is well known, much interest in the "light" treatment of skin diseases, and the committee is hoping that she will "lend her presence to the opening of the new hospital." Last year there were more than 57,000 attendances, 34,494 of which were by ordinary patients and 22,665 by "light" patients. They come from a very wide area. Bolton and Oldham each sent over 2300, Bury sent 1100, Stockport nearly 1000, while about 2500 were from Rochdale, Macclesfield, Burnley, Crewe, Warrington, Blackburn, and Northwich. During the year patients came from 250 towns and villages. This is mentioned in order to call attention to the great burden laid on the city charities by an outside population, thoroughly appreciative of the benefits to be derived from them but unfortunately not equally mindful of the fact that privileges involve duties and that the districts receiving benefits from medical charities should help in their support more liberally than many of them do at present. There was a deficiency last year of £270.

Coal Smoke Abatement Society.—At the Haymarket Theatre, London, W., on March 30th the Duke of Fife presided over the annual general meeting of the above society. The report stated that during the year a marked increase of interest in, and sympathy with, the object of the society had been shown. A supplementary report of the Meteorological Council on London fogs had been issued and its recognition of the society's work and its insistence that smoke was the main cause of those fogs which were bad enough to interfere with river traffic had encouraged the society to request the port sanitary authority to receive a deputation on the subject and that authority, which was showing great activity and interest in the matter, had readily consented. The help which the society received from public bodies generally was very satisfactory but the borough of West Ham provided a serious instance of official neglect. Since May, 1901, when the society began its observations there, 911 reports of serious emissions of black smoke within the area had been forwarded to the local authority, yet no effective steps of any kind had been taken to abate the evil. Every resource had been exhausted by the society to induce the Local Government Board to intervene, but notwithstanding the precedent of Brentford it refused to move in the matter. From Jan. 1st to Dec. 31st, 1904, the society's inspector reported 1550 observations of smoke pollution which led to the detection of 988 cases of nuisance, and upon those observations 949 complaints were forwarded to the various local authorities within the metropolitan area. In opening the proceedings the Duke of Fife congratulated the society on the work that it had done but complained that the society did not advertise itself enough. Until a few weeks ago he himself was unaware of its existence. On the motion of Dr. H. A. Des Vœux (the secretary) the report was adopted. The meeting terminated with votes of thanks to Mr. Cyril Maude, Mr. Frederick Harrison, and the chairman.

The Metropolitan Asylums Board and the Treatment of Consumption.—The much-discussed question as to whether the Metropolitan Asylums Board should be the authority for dealing with the consumptive cases in the metropolis has been raised again by the metropolitan branch of the Incorporated Society of Medical Officers of Health, which has asked the Board to receive a deputation on the subject. At a meeting of the Board on April 1st a letter was read from the society, stating that the question of the urgent need that existed at the present time for the provision of sanatoriums for metropolitan consumptives had been under discussion, and in view of the urgency of the matter it was decided to organise an influential deputation to wait upon the Metropolitan Asylums Board for the purpose of representing the desirability of the Board undertaking the duty of sanatorium authority for the metropolis at the earliest possible date. In coming to that decision the society was mainly influenced by the fact that the Metropolitan Asylums Board, by reason of its practical experience in regard to the provision of hospitals and the treatment of the infectious sick, was eminently qualified for the discharge of the important duty of dealing with metropolitan consumptives, a duty the effective performance of which could not fail to be attended with great advantages in the interests of public health. The letter further stated that the deputation would be composed of representatives from various public bodies, including the Royal College of Surgeons of England, the Royal College of Physicians of London, the National Association for the Prevention of Consumption and other Forms of Tuberculosis, the Royal Institute of Public Health, the National Health Society, and the Royal Sanitary Institute. The Board decided to receive the deputation at its meeting on Saturday, April 15th.

Dinner to Dr. F. T. Roberts.—On March 29th Dr. F. T. Roberts was entertained to dinner at the Hôtel Dieudonné by his past and present house physicians at University College Hospital. The chair was taken by Dr. F. W. Mott, F.R S., who was supported by about 30 former residents, including Mr. Charles Stonham, Mr. Percy Flemming, Dr. Walter W. H. Tate, Dr. W. T. Cocking (Sheffield), Dr. W. Mitchell Stevens (Cardiff), Dr. Bertram L. Abrahams, Dr. W. H. B. Stoddart, Dr. Charles Bolton, and Dr. D. N. Nabarro. Letters and telegrams were read from old pupils in India, Italy, and the provinces who had been prevented from attending. Dr. Roberts's health was proposed by the Chairman who referred to the fact that the master whom they were met to honour had been for 35 years, clinically speaking, one of the pillars of University College Hospital, and said that if he had not laid the bricks to the new building which was about to be opened he had at least cemented them with his brains. A time rule was about to sever Dr. Roberts's active connexion with the staff but he was still a young man both mentally and physically, and all who had ever worked under him hoped that he might for many years be spared to help them in consultation. Mr. Stonham also spoke to the toast and attributed much of his progress in surgery to the cultivation of his powers of observation to which he was incited by Dr. Roberts. He referred also with high appreciation to the standard of character which Dr. Roberts upheld and lived up to, so that all who experienced his kindness and straightforwardness were ever after the better for it. Dr. Roberts, who was accorded a *most enthusiastic reception, gave a short history of his* career. He stated that no fewer than 16 of his old house physicians were now on the staffs of general hospitals; to his residents and clinical clerks he owed much of the happiness which he had experienced during his long connexion with University College Hospital. Personally he hoped that he had never said an unkind word or done an unkind deed to anyone. He looked forward to the vacancy which his resignation would cause being filled by one of his former house physicians and he announced that far from giving up work he proposed, in addition to continuing his practice, to devote more time to writing than he had of late years been able to spare. He concluded by toasting the organisers of the dinner. Dr. Mott and Dr Abrahams responded. During the evening songs were contributed by Dr. Roberts himself, Dr. Mott, Dr. Tate, Dr. Banham, and Dr. Stoddart. An album, which it is hoped will contain signed photographs of all his old house physicians, is in preparation and will be presented to Dr. Roberts when complete.

DONATIONS AND BEQUESTS.—By the will of Mr. Henry Allen of Bolney, Sussex, £1000 are bequeathed to St. Mark's Hospital, £500 to the London Fever Hospital, £300 to St. Mary's Hospital, £300 to the Brompton Hospital for Cancer, and £100 to the Dorking Cottage Hospital.—The late Mr. Edward Crossley of Halifax has left £1000 to the Royal Halifax Infirmary and £500 to the Royal Isle of Wight Hospital.—The Goldsmiths' Company has contributed a special grant of £200 towards the debt of £3000 incurrred last year in maintaining the patients at the Royal National Hospital for Consumption at Ventnor.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Wilhelm Schulek, late professor of ophthalmology in the University of Budapest, at the age of 62 years.—Dr. Paul Garnier, chief medical officer of the Police Infirmary, Paris.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

Amendment of Infant Life Protection Act

A BILL to amend the Infant Life Protection Act, 1897, has been introduced by Mr SPEAR and has the support of Mr DUKE, Mr SCHWANN, Mr LINDSAY HOGG, Mr MELVILLE, Sir JOHN KENNAWAY, Mr MILDMAY, Mr. ALLEN, Sir JAMES FERGUSSON, and Mr. RUNCIMAN The following memorandum explains its scope. By the Infant Life Protection Act, 1897, a person receiving for hire or reward more than one infant under five years of age for the purpose of nursing or maintaining such infants apart from their parents for longer than 48 hours or receiving an infant under two years of age, to bring up in consideration of a sum of money not exceeding £20 paid down, is obliged to give notice thereof within 48 hours to the local authority, as defined in such Act Such local authority is obliged to appoint inspectors to inspect such infants Failure to give such notice renders the offender liable in the first mentioned case to a fine of not less than £5 or *to imprisonment for not* more than six months, and in the second mentioned case to only forfeiture of the amount received. If any infant, as aforesaid, is kept in any house or premises which are so unfit or overcrowded as to endanger his health, or is retained or received by any person who by reason of negligence, ignorance, or other cause is so unfit as to endanger the child's health, the local authority may order the removal of the infant to the workhouse or a place of safety until he can be restored to his relatives or guardians or otherwise lawfully disposed of The object of this Bill is to extend the provisions of the Act to cases where only one child is taken in to be nursed or maintained and to any child received in consideration of a sum of money paid down, whatever the amount may be; to raise to seven years the age limit of children within the Act, to render any person failing to notify the reception of an infant adopted in consideration of a lump sum payment to fine or imprisonment as above mentioned, as well as to forfeiture of the amount received; to make it clear that the inspection of children within the Act shall extend up to their reaching seven years or earlier removal by the local authority; to enable the local authority to remove an infant kept by a person who is unfit by reason of character or otherwise to have his care and maintenance or who is in a house or premises unsuitable *for the purpose, although* such person or premises are not so unfit as to endanger the child's health, and to require notice to be given of all changes of residence of a person having the care or custody of children within the Act under penalty of imprisonment or fine

Vaccination Bills.

Reference has already been made in THE LANCET to the two Vaccination Bills introduced by Mr. HENRY BROADHURST The texts have now been issued to Members In the first Bill the two operative clauses are as follow "1. From and after the passing of this Act the compulsory vaccination of children shall be abolished throughout the United Kingdom. 2 Henceforth it shall not be lawful to take proceedings for procuring the vaccination of any child or for punishing any parent or other person for not complying with any order for the vaccination of a child or with any statutory requirements for the vaccination of children" The second measure is somewhat more elaborate The second clause provides that "from and after the passing of this Act any parent may, on registering the birth of a child within the period limited by law and on payment of a fee of 1s, declare his or her conscientious objection to having the child vaccinated The registrar of births and deaths shall thereupon make a written memorandum of the said conscientious objection, such memorandum to contain the names and address of the parent and the dates of the birth of the child and of the registration thereof [illegible] registrar the memoran[illegible] necessary details [illegible] *of the* memorandum, one of such copies to be delivered to the parent making the declaration, a second copy to be retained by the registrar subject to any special or general instructions which may be issued by the Registrar General, and a third copy to be transmitted to the vaccination officer along with the list of births, which includes that of the child in respect of whom the declaration is made The local registrar of births and deaths shall be entitled to retain for his own use any fees paid under this section In the third clause it is laid down that after making such a declaration neither the parent who made it nor any person having the custody of the child in respect of whom the declaration has been made shall be liable to any proceedings in respect of the non vaccination of, or for procuring the vaccination of, the child It is not proposed that the measure should apply to either Scotland or Ireland.

The Accounts of Medical Councils

The accounts for 1904 of the General Medical Council and branch councils and of the Dental Registration Fund were laid upon the table of the House of Commons this week This is, of course, an annual formality

The Sale of Butter Bill

The Government Bill to amend the law with regard to the sale of butter has now been presented and read a first time When it will be read a second time is a question which the President of the Board of Agriculture himself might have difficulty in answering In the meantime its progress is blocked by Mr MACDONA, Sir JOHN ROLLESTON, and Mr MOSS

The Registration of Nurses

A select committee has been appointed on the initiative of the Government to consider the expediency of providing for the registration of nurses It consists of Mr ROBERT AMBROSE, Major KENNETH BALFOUR, Mr CHARLES DOUGLAS, Mr. CHARLES HOBHOUSE, Dr O F HUTCHINSON, Mr MOUNT, Lord MORPETH, Mr PIERPOINT, Mr TENNANT, Sir JOHN STIRLING-MAXWELL, and Sir JOHN BATTY TUKE The Bill on the subject which was introduced some weeks ago by a private Member has met an opponent in Mr HARRY LAWSON.

The London Hospitals and Rating

Mr HAYES FISHER has prepared a Bill to provide for the exemption of London hospitals from local rates.

Experiments upon Dogs

Dr HUTCHINSON has given notice of his intention to move the rejection of the *Dogs (Protection)* Bill

Medical Officers of Health and Inspectors

Another direction in which Dr. HUTCHINSON is exerting himself is in connexion with the qualification and tenure of office of medical officers and inspectors He has brought in a Bill on the subject

[illegible] tion to the Pharmacy Bill

[illegible] down blocking [illegible] opposition has been strengthened by the addition of the name of Mr. ALBAN GIBBS

The Sale of Whisky Bill.

Major JAMESON and Mr SAMUEL YOUNG have determined to do all they can to stay the progress of Sir HERBERT MAXWELL'S Sale of Whisky Bill. Both have notified their intention to move the rejection of the measure on second reading.

Amendment of the Lunacy Act.

On April 5th Sir JOHN BATTY TUKE introduced a Bill to authorise the London County Council to provide receiving houses for the reception of persons mentally afflicted or alleged to be of unsound mind and to authorise the detention of such persons in such houses *and for other purposes* connected therewith.

HOUSE OF COMMONS.

WEDNESDAY, MARCH 29TH.

Medical Officer for Long Island.

Mr. WEIR asked the Lord Advocate whether the Secretary for Scotland had yet received a report from the Lewis district committee relative to the appointment of a medical officer of health for the Long Island; and in the event of effect being given to the suggestion whether [illegible] the new officer to be responsible [illegible] and not to the medical officer of [illegible] to the firs [illegible] second part, I have nothing to add to [illegible] Member on March 14th.

The Residence of an Irish Medical Officer.

Mr. HEMPHILL asked the Chief Secretary for Ireland whether his attention had been called to a letter of Mr. John McGlinchy, dated March 6th, sending to the Local Government Board a petition signed by 220 ratepayers in the Castlederg and Killeter No. 2 dispensary district of Castlederg union, North Tyrone, relative to the place of residence of the medical officer, and complaining that his residence was on the bounds of the district, which imposed on many of the destitute poor when requiring medical aid the necessity of travelling up to 12 miles in all weathers for the purpose of obtaining it; and, if so, whether he would take the necessary steps to obviate this and to insure that the medical officer might take up his abode in a central position in his district which would be reasonably accessible to all the poor inhabitants who were entitled to medical aid.—Mr. LONG answered: The petition did not allege that any hardship to the sick poor had resulted from the position of the medical officer's residence. The officer in question has complied with the terms of his appointment by residing within his district and the Board sees no reason for interfering in the matter upon the facts at present before it.

The Prime Minister and Vaccination.

Mr. WEIR asked the First Lord of the Treasury whether, seeing that candidates for the public service were not allowed to take up appointments unless they had been vaccinated and that this regulation penalised candidates who had a conscientious objection to vaccination, he would take such steps as might be necessary to enable such candidates to obtai [illegible] said: I [illegible] the que [illegible] being v [illegible] underst [illegible] object?—Mr. BALFOUR: I can understand an objection to being vaccinated, just as I can understand objection to sleeping in an insanitary room; but the objection is not a conscientious one, it has nothing to do with conscience.—Mr. WEIR added that he would take an opportunity of referring to the subject and showing that it might be a case of conscience.

THURSDAY, MARCH 30TH.

An Admiralty Appointment.

Mr. CONOR O'KELLY asked the Secretary to the Admiralty whether he would state [illegible] the application of Mr. P. J. McHale, medica [illegible] strict, for the appointment of surgeon to the [illegible] was rejected, seeing that for 50 years the position was held by Mr. McHale's predecessors as local medical officer; why, contrary to invariable practice, a medical man living in another part of the country was appointed to the vacancy; and whether he would also state the fees now being paid to this medical man and the fees paid annually for the previous ten years; the number of coastguards to be attended; and whether, before appointing the present surgeon, the Admiralty made any effort to have the work done for less than what it was now paying.—Mr. PRETYMAN replied: The Admiralty did not consider that Mr. McHale was the most suitable gentleman for the post and it has never been the practice to appoint a man simply because his predecessor held the appointment of surgeon and agent. The present holder of the appointment is paid 10*s.* a visit. Previously the ordinary surgeon and agent's fees of 2*s.* 6*d.* per visit were allowed. It is not possible to state the precise amount paid in fees annually during the previous ten years without an elaborate investigation of records which would involve considerable clerical labour and time. The number of coastguards to be attended at the five stations under the surgeon and agent's charge is 30. The reply to the last part of the question is in the negative.

The Plague in India.

Mr. HERBERT ROBERTS asked the Secretary of State for India whether, in connexion with the scientific expedition to be sent out to India to investigate the origin and causes of plague, the coöperation of those in the areas affected possessing a knowledge of the difficulties of [illegible] would be sought; and whether [illegible] said: There seems to be some [illegible] and the scope of the inquir [illegible] plague were exhaustively dealt with by Sir Thomas Fraser's Commission of 1898-99 and the practical difficulties of combating the disease are familiar to the Indian Government and its officers. The present investigation will be confined to purely scientific problems in the hope that if these are solved advance will be made in the practical treatment of the disease. The composition of the expedition has been settled on the advice of the two scientific societies which have undertaken to supervise the inquiry, and I do not propose to add a [illegible] selected. The [illegible] will naturally [illegible] pect of matters [illegible] y.

MONDAY, APRIL 3RD.

The Conscientious Objector Again.

Mr. WEIR asked the President of the Local Government Board whether in view of the fact that mag [illegible] place differen [illegible] defined in the [illegible] which a man [illegible] child had been refused a certificate for another, although he had in each instance raised precisely the same conscientious objection to vaccination, he would consider the expedi [illegible] Act as to remove the difficulty experic [illegible] GERALD BALFOUR said: I believe that [illegible] gency of practice amongst magistrates in [illegible] the honourable Member is aware, the Lor [illegible] on the subject. In order to [illegible] of the magistrates through [illegible] friend the Home Secretary embodied them in a circular which he has issued to clerks of justices and I trust that the result of this action will be to secure greater uniformity in the practice of magistrates under the enactment in question. It does not appear to me to be necessary to amend the law on the subject.

Starving School Children.

Sir JOHN GORST asked the President of the Local Government Board whether it was not the duty of a relieving officer, in case a teacher informed him that a child under such teacher's care was destitute of necessary food, to inquire into the case, and [illegible] found the statement to be correct to give the [illegible] 896, [illegible] by the Board and its predecessors [illegible] ficers; whether such extracts [illegible] what, as to their duties with [illegible] ary food on whose behalf teachers made application for relief; and if they did not contain such information whether he would either cause the circular containing such to be issued or indicate in what book accessible to relieving officers it could be found.—Mr. GERALD BALFOUR answered: The orders provide that it shall be the duty of a relieving officer to receive all applications for relief made to him within his district or relating to any parish within his district and forthwith to examine into the circumstances of every case by visiting the home and making [illegible] report the result of such inquiries to the [illegible] linary meeting. The orders also provide [illegible] very case of sudden or urgent necessity to afford such relief to the destitute person as may be requisite, provided that the same be not given in money. It would be incumbent on a relieving officer to act in accordance with these requirements if application were made to him by a teacher for relief to a child under the teacher's care [illegible] The extracts from the orders is [illegible] tained the provisions to which I [illegible] fer specifically to cases of the kind mentioned in the question. The Secretary of the Board of Education and I have been in communication in regard to such cases and I am now considering whether any further steps should be taken in connexion with them and whether a circular should be issued on the subject.

Dr. MACNAMARA asked the First Lord of the Treasury whether his attention had been called to the Bill introduced [illegible] for the Barnard Castle division designed to [illegible] authorities to make provision out of the func [illegible] feeding of hungry children and to empower them also, where it might seem desirable, to recover the cost from the parents and guardians of children so fed; and whether, having regard to the unanimous recommendations of the Royal Commission on Physical Training (Scotland), 1903, a [illegible] grant [illegible] BALFO [illegible] appointed to examine into the facts of this question and I do not think that pending the report of that committee I can make any statement on the subject.—Sir JOHN GORST: Is it not a fact that the committee appointed by the Board of Education is specially precluded from considering any scheme which would cast a charge on the public funds?—Mr. BALFOUR: The main object of the committee is to inquire into the facts and it is, among other things, a real knowledge of the facts that we require before dealing with a subject which is of itself of a difficult character and touches very [illegible] all sides.—Dr. MACNAMARA: Can the rig [illegible] hold out any prospect that this committee [illegible] of the present session?—Mr. BALFOUR: No, Sir, I cannot make any promise on the subject. It does not rest with me.

An Irish Admiralty Appointment.

Mr. CONOR O'KELLY asked the Secretary to the Admiralty whether he would state the professional qualifications of the surgeon to the Admiralty at Belmullet; what previous experience in the practice of his profession he had, and where, bef [illegible] which caused the Admiralty to cons [illegible] Studdert more suitable than that of [illegible] fees received by Mr. Studdert during [illegible] the total sum in fees received by Mr [illegible] in that position.—Mr. PRETYMAN replied: The professional qualifications of the Admiralty surgeon and agent at Belmullet are Lic. Lic. Midwif. R. Coll. Phys. Ireland; Lic. Lic. Midwif. R. Coll. Surg. Ireland. He had had previous experience at High Wycombe and Sheffield and was recommen [illegible] after careful inquiry, as being the [illegible] l sum in fees received by Mr. Studd [illegible] urgeon and agent was £178 and the total sum in fees received by Mr. Lavan in his last 12 months in that position was £140 2*s.* 6*d.*

The Irish Constabulary and Medical Attendance.

Mr. SLOAN asked the Chief Secretary for Ireland whether he would state how many th [illegible] r the exp [illegible] direct inquiry to [illegible] past three years [illegible] eir own expense. [illegible] The inspector-general's attention has already been called to this matter and he is inquiring into it.

Return of Small-pox Outbreaks.

Sir JOHN TUKE asked [illegible] Board whether he would be [illegible] places in which cases [illegible] months, giving the total number of cases occurring in each place in which that number had reached or exceeded 100.—Mr. GERALD BALFOUR said: I am willing to give a return on this subject and I

floors have been removed and replaced by terazzo paving. The work was commenced in 1899 and completed in 1902.

Vaccination Fees in Ireland.

Mr. SLOAN asked the Chief Secretary for Ireland whether he could say what had been the cost to Ireland and Scotland respectively for vaccination fees since the year 1845.—Mr. LONG replied: The total amounts of fees paid in Ireland to March 31st, 1904, was £351,643. I have no information as to the amount of fees paid in Scotland.

The Analysis of Irish Butter.

counties. Clare, Galway, Kerry, Limerick, Tipperary (N.R.), and

ater. In the remaining samples the proportion of water exceeded 20 per cent. These facts show how small is the number of cases in which the water in the butter exceeds the 16 per cent. limit prescribed by the regulations under Sections 4 and 24 of the Sale of Food and Drugs Act, 1899, which are in force both in Great Britain and Ireland.

DEATH.

MATTHEWS.—On March 31st, at Sudbury, Suffolk, Alec Leslie Matthews, F.R.C.S., L.R.C.P., of the London Hospital, late of Norwood, aged 31.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

MOSQUITO MALARIA THEORY 1400 YEARS OLD.

IN the course of an address given at the annual meeting of the Ceylon branch of the Royal Asiatic Society, the Governor of the island, Sir H. Arthur Blake, made the following highly interesting remarks:—

> They prided themselves upon the enormous strides that had been made in science of late and especially within the last wonderful century; and among those discoveries there had been none of greater importance than the discoveries made in medicine and hygiene; and among those discoveries he did not know of any that had attracted more attention than the results of the investigations into that fatal and widespread disease that had afflicted humanity perhaps more than any other, by Manson, Ross, Celli, and others—malarial fever caused by the bite of the mosquito. The question to be asked was, Are we not merely recovering the crumbs of knowledge that fell from the table of the long buried East? A short time ago Government instituted an inquiry into the incidence of malarial fever at Mutwal and during the inquiry he was surprised to see a communication from the Secretary of the Ceylon Native Medical Association mentioning that in old books the mosquito was mentioned as one of the means of propagating malarial fever. He was so struck that he made further inquiries and found that in the medical work of Caraka Susruta and other ancient Sinhalese writers it was mentioned that there were 67 kinds of mosquitoes, and further that there were four kinds of malarial fever caused by the bite of those mosquitoes. At present about 36 to 40 species had been named in Ceylon, of which Mr. Green had named 24. So that, as a matter of fact, recent discoveries were only re discoveries. The books he referred to were written in the sixth century; therefore they had only re discovered what was on record 1400 years ago. Those facts were rather interesting and he did not know whether any of those present could read Sanskrit, but the Interpreter Mudahyar was there and the books were there and the passages were there, showing from where they had been derived.

A POSSIBLE DEVELOPMENT OF SERUM THERAPY.

To the Editors of THE LANCET.

SIRS,—Could any of your readers tell me whether there is anything opposed to the suggestion that the serum of a man or an animal, protected (by use and habit) against poisonous doses of morphine, arsenic, &c., would protect a normal individual against similar doses? Also whether any experiments have ever been made on these lines and the results published.

I am, Sirs, yours faithfully,

INQUIRER.

April 4th, 1905.

THE LORD OF THE MANOR'S HERIOT AT AN INQUEST.

To the Editors of THE LANCET.

SIRS,—The letter addressed to you in THE LANCET of April 1st, p. 900, is full of interest. A heriot was the best beast due to the lord of the manor at the death, natural or otherwise, of the copyholder, the second best being frequently bequeathed to the Church as a cors present. This is one thing, but in the inquest reported by your correspondent a totally different state of affairs presents itself, inasmuch as "the Jury brought in the unlucky Beast in Value as low as Three pounds, thinking that sum would be a compencation to his Lordship." The fact that the jury valued the animal points strongly in favour of the stag being a deodand—not a heriot; in other words, as the guilty party causing the death and liable to forfeiture apart from any manor custom. In these circumstances there would appear to be a little confusion between "*one of his own Horses*" and "the stagg." It may be that a horse was suspected, but in evidence given at the inquest the stag was proved guilty. A stag was not usual as a heriot. I have dealt at some length on this topic in my recent book, "The King's Coroner," pp. 6–8 and 204–5.

I am, Sirs, yours faithfully,

R. HENSLOWE WELLINGTON,
Barrister-at Law and Deputy Coroner.

Essex-court, Temple, E.C., April 3rd, 1905.

To the Editors of THE LANCET.

SIRS,—The "stagg" paid to the lord of the manor by Dr. J. J. Udale's ancestor could not have been a heriot. The heriot was the best beast belonging to the tenant, and to this the lord had a right on the death of the tenant, or on the succession of the heir, or both. In the case of Dr. Udale's ancestor, the "stagg" was not taken as of right by the lord, but was awarded to him by the inquest. This was the procedure regulating the transfer, not of heriots, but of deodands. A deodand was the instrument which had caused the death of a human being and which thereupon became forfeit to the king, by whom it, or its value, was to be handed over to the poor. This was clearly interpreted to mean the poor in spirit, for it is certain that the sovereign granted to many lords of manors the right to receive deodands. In the case related, it was a horse which caused the death and yet the deodand awarded by the inquest was a "stagg." We can only conjecture the reason. It may have been that the horse had already been seized by the lord as a heriot; or it may have been that the inquest desired to curry favour with the lord by awarding something more valuable, or to show consideration for the tenant's family by awarding something less valuable. The share of the inquest in awarding the deodand is obvious. The deodand was the instrument which had caused death. The cause of death was not ascertained until the inquest had formally declared it. The deodand was contingent on the verdict.

I am, Sirs, yours faithfully,

Catford, April 2nd, 1905. CHAS. MERCIER.

To the Editors of THE LANCET.

SIRS,—I have read with interest the letter in THE LANCET of April 1st, p. 900, on the subject of "The Lord of the Manor's Heriot at an Inquest" and would like to add something which I have found in some old books in the library attached to the Royal Devon and Exeter Hospital. In the "Medical Jurisprudence," dated 1823, at London, by J. A. Price, M.D., &c., and J. S. M. Fonblamque, Esq., barrister-at-law, on the subject of the coroner's inquest, one reads:—

> "The Coroner, amongst other things, must enquire of the deodand, (the gift to the Gods,) which, on the violent death of anyone, even though purely accidental, has accrued to the King or his grantee. This mulct was in ancient times applied to the purpose of purchasing masses for the repose of the soul of the deceased; it is now converted into an ill-apportioned, arbitrary, or in a few cases, inadequate fine on the individual whose property has been, whether innocently or culpably, the cause of death. It is as absurd, that a ship under sail, from which a man has fallen, and been drowned, should be forfeited to the King, as if ...... where a thing is not in motion, that part which actually caused the death, is alone forfeited, as if a man be climbing on the wheel of a cart, and is killed by falling from it, the wheel alone is a deodand. But whenever the thing is in motion, not only that part which immediately gives the wound, (as the wheel which runs over his body,) but all the things, which move with it, and help to make the wound more dangerous, (as the cart and loading, which increase the pressure of the wheel,) are forfeited ...... it matters not, whether the owner were concerned in the killing or not. But juries have of late, frequently taken on themselves to mitigate these forfeitures, by finding only some trifling thing, or part of an entire thing, to have been the occasion of the death."

Paris does not explain the word "stagg" in his work but in an old book on folk-lore in the museum here one finds that it was in use in Cumberland to signify a horse under three years of age. In the case quoted the horse being under three years was the "stagg," and being the cause of the man's death was forfeited as a deodand to the King or his grantee. I am, Sirs, yours faithfully,

W. HUDSON MARSDEN,
Assistant House Physician at the Royal Devon
Exeter, April 4th, 1904. and Exeter Hospital.

THE CASE OF DR. A. D. GRIFFITHS.

To the Editors of THE LANCET.

SIRS,—Will you kindly allow me to acknowledge the receipt of the following additional contributions? Mr. W. C. Griffiths, 10*s.* 6*d.*; Dr. J. Shaw Lyttle, 10*s.* 6*d.*; already acknowledged, £70 14*s.* 6*d.*

I am, Sirs, yours faithfully,

ALEX. P. FIDDIAN, M.B. Lond.,
23, The Walk, Cardiff, April 4th, 1905. Honorary Treasurer.

A CRUSADE AGAINST PHTHISIS.

To the Editors of THE LANCET.

SIRS,—Can any of your readers tell me where I can procure "A Crusade against Phthisis" by Dr. Gerrish (?) I do not know the publisher's name and am uncertain of the author's.

I am Sirs, yours faithfully,

April 3rd, 1905. H. W.

DOVER AS A HEALTH RESORT.

To the Editors of THE LANCET.

SIRS,—In reply to "Paddington" I beg to say that if he will refer to Whitaker, fol. 762, he will find a condensed report of Dover as a health resort. In accordance with statutory requirements the medical officer of health issues a yearly statistical report which is printed and circulated amongst those for whom it is specially prepared.

I am, Sirs, yours faithfully,

M. K. ROBINSON, M.D. Erlang.,
Dover, April 3rd, 1905. Medical Officer of Health.

To the Editors of THE LANCET.

SIRS,—In answer to the letter of "Paddington" with respect to Dover as a health resort, I should like to say that the climate of Dover is excellent. The rainfall is small. The water-supply is absolutely pure and comes from the hills in the neighbourhood. The soil is for the greatest part chalk. The death-rate is, and has been for a long while, very low. The medical officer of health presents statistics every year and I expect they are published. I consider Dover a very desirable place residentially.—I am, Sirs, yours faithfully,

J. REGINALD LONG, M.R.C.S. Eng., L.R.C.P. Lond.
Dover, March 31st, 1905.

THE VERAWILL FOOT-ROLLER.

WE have had submitted to us an apparatus under the above name. It consists of two rollers of about the diameter of an ordinary cylindrical ruler. They are made of wood mounted in brass and are fixed to a heavy wooden base. The method of using the apparatus is to place it on the floor and to roll the feet slowly backwards and forwards, using at the same time the hinge-motion at the ankle-joint somewhat after the proper method of pedalling on a bicycle. In this way the soles of the feet are massaged and the muscles of the calf, together with those on the front of the leg, are exercised. From a personal trial we can say that the use of it produces a pleasant warmth in the foot and we should think that it would be of benefit to those who suffer from cold feet, while it would also be a useful adjunct to the usual exercises prescribed for flat-foot. The price is 12*s.* 6*d.* and the apparatus can be obtained at 165, Victoria-street, London, S.W.

MEDICAL WRITINGS BY MARAT.

To the Editors of THE LANCET.

SIRS,—The Royal College of Surgeons of England in 1891 reprinted two pamphlets, originally written by Jean Paul Marat, M.D., in 1775-76. The names of the pamphlets were: "An Essay on Gleets" and "An Inquiry into the Nature, Cause, and Cure of a Singular Disease of the Eyes." The writer was the well-known French revolutionary agitator Marat.

I should be obliged if any of your readers could inform me through your columns whether these are of any value.

I am, Sirs, yours faithfully,

Camden-road, N., April 2nd, 1905. HARRY JONES.

◆

J. C.—The Departmental Committee on Food Preservatives in its report issued in 1901 came to the conclusion that as regards the trade in fresh and cured meat, fish, butter, margarine, &c., there exists no sufficient reason for interfering to prevent the use of boron preservatives. The limit recommended in the case of butter was 0 5 per cent. of boric acid, and cream 0·25 per cent. No limit was mentioned in the case of other foods and although the above limits are practically accepted in proceedings under the Sale of Food and Drugs Act they are not as yet statutory.

Enquirer.—We have no knowledge of the matter except what is stated at p. 403, vol. ii., of "The Life and Letters of Thomas Henry Huxley," Macmillan and Co., 1900, to which our correspondent is referred.

Locus Standi.—The extent to which botany is necessary in the medical curriculum is now under debate. We think too much has been required of the student.

R. J. F.—The lay press constantly make errors in medical titles and when we remember the anomalies connected with these titles we can hardly be surprised.

Mr. W. C. Lewis.—We take no interest in remedies where the alleged discoverer wishes to patent a proprietorship.

Fresh Air.—We think that the suggested recommendation would not be advisable.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (10th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopædic (4 P.M.), Gt. EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTICE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

METEOROLOGICAL READINGS.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31, Rue Bapts, Asnières Paris.

The Goulstonian Lectures

ON

SOME CONSIDERATIONS ON THE NATURE OF DIABETES MELLITUS.

Delivered before the Royal College of Physicians of London on March 16th, 21st, and 23rd, 1905,

By W. CECIL BOSANQUET, M.A., M.D. Oxon., F.R.C.P. Lond.,

ASSISTANT PHYSICIAN TO CHARING CROSS HOSPITAL AND TO THE BROMPTON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST; FORMERLY FELLOW OF NEW COLLEGE, OXFORD.

LECTURE II.[1]

Delivered on March 21st.

Mr. President and Gentlemen,—In my former lecture I alluded to the relationship of diabetes to changes in some of the organs of the body which I ventured to think were effects rather than causes of the disease. I have to deal to-day with a more important organ in relation to diabetes—*the pancreas.* Attention was first called to the association of pancreatic disease with a case of diabetes by Cowley in 1788. In this instance the pancreas was found to be atrophied and to contain calculi in its ducts. Claude Bernard discovered that removal of the pancreas in animals was followed by a condition similar to diabetes (1855). The first observer, however, who definitely formulated a theory of diabetes as dependent upon disease of the pancreas was Lancereaux (1877). Subsequently (1889) the experimental side of the question was fully worked out in the classical labours of von Mering and Minkowski; their experiments have been often repeated and their results have been fully confirmed, but little has been added to the sum of our knowledge in this field by the work of their successors. The work of von Mering and Minkowski is so well known that it is unnecessary to do more than to allude briefly to the conclusions that may be drawn from it. They proved that total extirpation of the pancreas in dogs and other animals is invariably followed by a condition exactly resembling diabetes—a condition in which there is not only sugar in the urine, dependent upon excess of sugar in the blood, with the ensuing symptoms of increased appetite and thirst, but also an acid intoxication, with the appearance of acetone and diacetic acid in the urine and a tendency to death in coma. Partial extirpation of the pancreas was not followed by this condition, nor was total ablation of the gland if a fragment of it were grafted into some other part of the body; if, however, as usually takes place, this grafted fragment ultimately disappeared, then diabetes ensued as certainly as if the gland had been removed at one operation. Similarly, if the gland be removed in three separate pieces on different occasions diabetes does not occur till the last piece has been taken away. That this effect is not due to the absence of the digestive juice furnished by the pancreas is sufficiently shown by the phenomena which ensue after ligature of the ducts. In most cases no diabetes or glycosuria is observed; in a few instances there is a transient glycosuria with some increase of appetite and thirst but this passes off within a few days. It was, indeed, objected to these last experiments that the ducts generally re-establish themselves after ligature or section, so that the secretion may once more reach the intestine. To obviate this various experimenters have injected the ducts with substances such as paraffin, soot, and tarry materials (Schiff, Thiroloix, Gley) which produce permanent obliteration of the secretory channels, without causing the appearance of diabetes. Thiroloix, indeed, maintains that by these means it is possible to produce a total atrophy of the pancreas and that yet no diabetes ensues. It is probable, however, that the disappearance of the glandular tissue was not really so complete as he supposed. In some experiments it has been observed that merely separating the pancreas from the duodenum, or handling it, or disturbing it in its relations, may result in the temporary appearance of glycosuria.

It seems to be absolutely proved by these experiments that removal of the pancreas is followed in animals by a condition indistinguishable from diabetes. It is necessary therefore to examine how far clinical and pathological evidence point in the same direction in the case of mankind. Lancereaux in his work on "Diseases of the Liver and Pancreas" described four different conditions of the pancreas which may exist in cases of *diabète maigre* or wasting diabetes—as [illegible] of the disease, or rather, in [illegible] glycosuria, met with in fat perso[illegible] atrophy or aplasia of the gland, in which the cellular elements are diminished in number without any accompanying alteration in the structure of the organ or in the appearance of the cells; (2) atrophy with fibrosis (secondary sclerosis) of the gland and some fatty degeneration of its cells; (3) atrophy with inflammatory fibrosis, the result of infective processes or obliteration of the ducts; and (4) tumours, especially cancer of the head of the pancreas which has led to obstruction of the ducts. This observer, therefore, especially associated *atrophy* of the pancreas with diabetes, though it would seem that he attributed undue importance to disease of the ducts.

Of recent years much attention has been paid to diseases of the pancreas which are now better understood than of old. The chief pathological changes found in it are now recognised to be. atrophy, carcinoma, cystic disease, acute and chronic inflammation, calculi affecting the ducts, and hæmorrhage into its subst[illegible] connective tissue. It may [illegible] and may be the seat of [illegible] It is necessary [illegible]e co-existence of [illegible]d diabetes. The latter is a somewhat rare disease, though not apparently so rare now as in the time of Galen who only saw two cases of the malady.[2] Still, the total mortality from diabetes is somewhere about 7 per 100,000 of the population (Saundby). Among patients admitted to Charing Cross Hospital I find that diabetics, or those who are so classed, amount to about 6 per 1000 of the whole number of admissions It has been argued that as diabetes is a rare disease and lesions of the pancreas are also not frequent, the co-existence of the two in any considerable number of cases *ipso facto* renders the causal connexion between them highly probable. But is it certain that pancreatic disease is uncommon? I thought it worth while at the time when I was making post-mortem examinations at Charing Cross Hospital and elsewhere to investigate the question, and with this object I cut sections for microscopical examination of the pancreas from 100 practically consecutive cases. Most of them were from cases on which I myself made necropsies, but some were kindly sent me from Claybury Asylum by Dr. Bolton, by permission of Dr. F. W. Mott, these cases also being consecutive and not in any way selected. Some of my own cases were from the Victoria Hospital for Children and a few from the Samaritan Hospital for Women, at both of [illegible] the time. The series was thus [illegible] any one hospital but consisted [illegible] for examination of the point in question. Their ages ranged from four days up to over 90 years. I had hoped to be able to supplement this very inadequate number from which to draw conclusions by examining the records of necropsies at other hospitals; but I soon came to the conclusion that unless a microscopical examination of the pancreas were made it was impossible to say in any case whether it was normal or not, since in many instances the external appearance of the gland might be unchanged in the presence of considerable alterations in minute anatomy. I therefore felt that statistics of the number of cases in which this organ was healthy or unhealthy could not be safely collected from the records of other hospitals, as it is practically impossible to make microscopical examinations of all organs in every case, and it would not be likely that such examination of the pancreas would be made unless there were some gross alteration in its appearance to cause attention to be directed to it. I have had, therefore, to be contented with my own 100 cases. Among them I found a certain degree of fibrosis present in 15. Of these ten were over 40 years of age, counting among these two whose ages were not actually known, but who appeared to belong to this period of life. It would seem from this that a certain amount of fibrosis of the pancreas is not very uncommon, occurring in some 15 per cent. of patients dying from all causes in hospital, while among persons over 40 years of age it is much more often met with (ten out of 54) than in those below this age. In 70 cases (not quite consecutive) which I have since examined the proportion in which I found fibrosis of the pancreas present was approximately the same as in the first 100. The youngest patient in the former series in whom I found any increase of fibrous tissue present was aged 29 years and in this case there was a special reason for such a pathological condition in that he was almost certainly a syphilitic subject. That syphilis may be a cause of pancreatic fibrosis is practically certain as a congenital fibrosis of this organ is met with and has been described by Opie. It appears to be a fatal lesion, the infants succumbing within the first few days after birth. No records seem to exist as to the presence of sugar in the urine of such infants. Since the pancreas is thus affected in infancy it is highly probable that in the adult also it, like other organs, will undergo cirrhosis as a result of this disease. Another comparatively young patient in my series who exhibited some fibrosis of the pancreas died from a ruptured aneurysm, which occurrence affords a ground for suspecting the existence in this instance also of a syphilitic taint.

---

[1] Lecture I. was published in The Lancet of April 8th, 1905, p. 903.

[2] This would seem to prove that Galen distinguished diabetes from mere polyuria, of which he could not have failed to observe many instances.

If the results suggested by a small number of figures which I have been able to collect are borne out by further investigation, it would seem likely that a certain amount of fibrosis of the pancreas is a usual accompaniment of advancing age. Possibly it is preceded by some atrophy of the glandular elements, the fibrous tissue merely taking the place of higher cells which have disappeared. The condition may thus be correlated with fibrosis of the arterial system and with chronic granular kidney. Atrophy with secondary fibrosis was assigned by Lancereaux as one of the causes of diabetes. It is interesting to remember in this connexion that diabetes is usually a disease of advanced life so that its incidence somewhat corresponds with that of pancreatic fibrosis. It is clear, however, that some fibrosis of the pancreas may exist without diabetes, for only two cases of that malady came into my series of 100 cases. I did not find any traces of fibrotic change in the pancreas in any of the children whom I had the opportunity of examining; but apart from the congenital syphilitic form of pancreatic fibrosis, an acquired form of fibrosis does seem to exist, as was proved to me by a specimen sent me by Dr. A. D. Jollye of Brixton for examination. This was taken from a child, aged seven years, who had suffered from severe tetany during life. At the necropsy the only visible pathological condition was in the pancreas which was much enlarged. On examining it microscopically I found that it was the seat of marked fibrosis. The cause of this was not ascertainable, though it was impossible not to think of syphilis in view of the irregular distribution of the fibrous tissue. Whether the pancreatic condition had any relation to the tetany was also problematical. This disorder is usually attributed to the absorption of some toxic material from the stomach and it is possible that an affection of the stomach and duodenum was followed by secondary cirrhosis of the pancreas by extension of inflammation up the duct of Wirsung. Diabetes in children is not common. When it occurs it is rapidly fatal as a rule, suggesting the existence of some extensive or progressive lesion of the pancreas if this organ be at fault.

Opie has distinguished two varieties of fibrosis of the pancreas: (1) one, a coarsely distributed variety, in which the fibrous bands pass between the lobules of the gland, embracing groups of acini in their meshes; this he calls the "interlobular" variety; and (2) a more finely distributed fibrosis in which the new tissue passes between the individual acini ("interacinar" fibrosis). He considers that diabetes is related to the latter (for reasons which I shall mention later), not to the former. The varieties of pancreatic fibrosis are thus somewhat analogous to the types of cirrhosis of the liver, in which we recognise a multilobular or portal cirrhosis, with coarsely distributed bands of fibrous tissue, and a unilobular or biliary cirrhosis in which the fibrous network penetrates between the single lobules. In the latter the liver is often much enlarged, whereas in the former it is generally shrunken if the cases have lasted long. The same appears to be true of the pancreas. The common form of fibrosis is accompanied by shrinking of the gland and often by atrophy or fatty degeneration of the cells. But the organ may, on the other hand, be considerably enlarged. In one case of diabetes, which I had the opportunity of observing before I began to collect a series, the pancreas was of vast dimensions, weighing just one pound instead of some three or three and a half ounces. It was thus more than four times its usual weight and was tough and hard in consistency. Microscopically it was seen to be penetrated by new bundles of fibrous tissue, both coarsely and finely distributed. I shall refer to the details of the case a little later. It may be remarked that the pancreas is an organ in which it is difficult to be certain of the reality of slight degrees of fibrosis, as the connective tissue in it is normally somewhat irregularly distributed.

With regard to the relation of *atrophy* of the pancreas to diabetes Hansemann distinguishes two varieties of atrophy of the gland: (1) one in which there is simple wasting of the cells, and (2) a second in which this wasting is accompanied by fibrosis. The former occurs in cases of general failure of nutrition and is a secondary change; it may be called "cachectic" atrophy. The pancreas is found to exhibit a rounded, almost cylindrical form and to be of normal consistency. It is sharply marked off from surrounding parts and is easily removed from the body, being free from adhesions to neighbouring structures. The cells and lobules are shrunken but the organ is not pigmented, nor is it fibrous. In the second form of atrophy the pancreas is soft in consistency and dark in colour; it is flattened from before backwards and is closely adherent to surrounding parts. The gland is permeated by an increased amount of fibrous tissue and there may be some cellular infiltration. The condition thus somewhat resembles that of a granular kidney which is fibrous and adherent to the tissues surrounding it and, like granular kidney, it is very probably related to arterio-sclerosis. It is this latter variety of atrophy which is associated with diabetes. In other words, although Hansemann lays stress upon the atrophy it would seem to be fibrosis of the pancreas which is the principal lesion associated with diabetes—a condition apparently analogous to the atrophic form of cirrhosis of the liver. In both organs, however, there seems no means of determining whether the atrophy of the cells leads to increase of fibrous tissue, as in the case of the nervous system, or whether the fibrosis is of an inflammatory nature and contraction of the scar-tissue produces injurious pressure upon the glandular acini.

Fatty degeneration of the pancreas—using the term "degeneration" in a wide sense without determining whether it is an infiltration, so-called, or metamorphosis—is not uncommon. Among my 100 cases I found a recognisable degree of fatty change present in ten instances; in three cases it was combined with some fibrosis. A case of diabetes dying in coma exhibited very advanced fatty change along with fibrous overgrowth, and some degree of fatty degeneration was present in most of the cases of diabetes which I have examined. In fat persons the gland is not infrequently penetrated by columns of fatty connective tissue passing between the lobules, but the cells of the acini appear normal. Hansemann notes that in a few cases of diabetes fatty degeneration of the pancreas has been found after death as the only discoverable lesion.

Calculi in the pancreatic ducts have been associated with a certain proportion of cases of diabetes. Thus, as already mentioned, the original observation of Cowley was of this condition. Hansemann notes that out of 72 cases which he collected from medical literature calculi were the cause found in 14 instances. It is clear that these concretions cannot exert a direct action on the process of sugar-formation, since all that they can do is to block the ducts; and, as has already been mentioned, ligature of these does not seem to be an efficient cause of diabetes or lasting glycosuria. But the continued existence of obstruction to the outflow of secretion is accompanied by injurious pressure in the acini, analogous to the condition present in the kidney in cases of obstruction to the exit of urine. In both organs alike cystic dilatation of the ducts and atrophy of the secreting cells ensue, accompanied by an overgrowth of fibrous tissue. It is to this atrophy of the glandular cells that the diabetes associated with calculi must be attributed. It has, however, been found experimentally that injection of pancreatic juice into the ducts of the organ is followed by the appearance of sugar in the urine, so that a temporary glycosuria might ensue as the result of impaction of a calculus before any destructive changes occurred in the organ; this glycosuria might pass off if the calculus escaped or was removed, or it might become permanent if no such relief was afforded.

Carcinoma of the pancreas is not a very infrequent condition as a primary lesion. Secondary growths of cancer in this organ do not seem very common. I have met with two [illegible] of sarcoma in this position; in [illegible] was in the thyroid gland, but [illegible] coincidence. The relations of carcinoma of the pancreas to glycosuria are somewhat curious. The latter symptom is not constant; it may appear late in the history of the case or it may be noticed early and pass off again. The absence of permanent diabetes in many—indeed, in most—cases of cancer of the pancreas is probably due to the fact that the disease does not destroy the pancreatic cells entirely; in the most extensive cases the new growth rather insinuates itself between the cells so as to obliterate the normal structure of the organ, while in the majority of instances the tumour remains limited to one part of the gland, usually the head, leaving the rest unaltered. The temporary glycosuria observed depends in all likelihood upon interference with the outflow of pancreatic juice which, as has just been mentioned, may produce glycosuria. In many instances of primary cancer there is coexistent fibrosis of the pancreas along with the new growth and it is difficult to ascertain which was the primary condition—whether the cancer produced the fibrosis by obstruction of the ducts of the gland, as a calculus may do, or whether the new growth arose in a fibroid organ, as seems to be the case most frequently in primary cancer of the liver, the tumour originating in all probability in a group of cells isolated by the fibrous overgrowth similar to the groups seen in the so-called multiple adenomata of the cirrhotic liver.

Hæmorrhage into the pancreas may be associated with the appearance of sugar in the urine. The following case may be quoted as an example. A laundress, aged 53 years, was admitted into Charing Cross Hospital under the care of Dr. J. M. Bruce on Jan. 24th, 1893, complaining of abdominal pain, thirst, and dypsnœa. Her previous history had been uneventful; there was no history of syphilis. A week before admission to hospital she was seized with pain in the abdomen which rapidly swelled and became hard to the touch. At the same time she complained of increased thirst and of shortness of breath and had a difficulty in getting about. On examination she appeared to be a well-nourished woman; her face was flushed and her tongue was dry and covered with brown fur. Her temperature was 100° F. and she complained of great thirst. There was pain all over the abdomen, which was uniformly distended, so that the umbilicus was obliterated. Tenderness was general over the abdomen, but there was increased resistance in the epigastrium and hypochondria, especially on the right side. The bladder was distended and the edge of the liver could be felt about one and a half inches below the costal margin. She was delirious at night, trying to get out of bed continually. She passed from 54 to 60 ounces of urine per diem, the total amount of sugar present varying from 1012 to 1125 grains. Her temperature gradually rose, and on the 29th and 30th she had rigors. On the latter day acetone was noted to be present in the urine. She vomited and became very restless. Finally she died in collapse without any appearance of coma. At the necropsy there was found "a good deal of turbid fluid in the peritoneum; some little lymph between the coils of the intestines." The layers of the mesentery were everywhere, separated by a large mass of disintegrated blood clot and blood-stained fluid. The stomach was adherent to the left lobe of the liver and on separating the two several pints of blood-stained grumous fluid escaped. "The fat was everywhere speckled over with opaque dead-white points which appeared to be composed of necrosing fat. ...... In the situation of the pancreas was a breaking-down mass of tissue along with much bloody fluid. Some loose shreds of tissue as big as a fist were floating in this cavity; they appeared to be portions of the pancreas." No other morbid conditions were found.

In this case, therefore, there was destruction of the [illegible] diabetes before the sudden onset of the illness; yet on her admission to hospital she exhibited all the signs of the malady—thirst, glycosuria, and finally acetonuria. Such a case constitutes a natural experiment on removal of the pancreas in a human being and the results exactly correspond with those obtained in animals. Here, at least, the connexion between a lesion of the pancreas and the onset of diabetes appears to be absolutely proved. The death of the patient was apparently due to the peritonitis accompanying the necrosis of the pancreas and not to the diabetes, as the patient did not die in coma but in a state of collapse. The presence of acetone in the urine in such a case appears to show that no distinction, such as that quoted from Professor Tyson in my first lecture, can be drawn between pancreatic diabetes and "severe diabetes accompanied by acid intoxication." Experiments on animals show that the latter phenomenon is characteristic of pancreatic defect.

If we examine the results of observations as to the coexistence of gross lesions of the pancreas with diabetes, we find very different figures given by different writers. Hansemann, who carefully studied the question and formed the opinion already alluded to that a special form of atrophy with fibrosis was characteristic of the disease, found alterations of the pancreas present in 40 out of 59 cases. Windle found 74 cases of pancreatic disease out of 139 cases; Frerichs, 12 out of 40; Seegen, 17 out of 92; and Naunyn, 1 out of 40 (I quote the figures from Professor Tyson). It seems almost impossible to reconcile the figures given by Naunyn with those found by others. I have not myself had the opportunity of examining many cases of diabetes post mortem since undertaking this inquiry; but of seven cases in which I have examined the pancreas I found distinct alterations present in five, consisting in fibrosis of varying degrees with some fatty change. In a sixth case, that of an old man with advanced arterio-sclerosis and gangrene of the leg, the vessels in the pancreas were markedly sclerosed; the glycosuria had been intermittent. It might be suggested that this was due to intermittent pancreatic failure, analogous to the "intermittent claudication" sometimes met with in arterio-sclerosis. In the remaining case I was unable to discover any noteworthy pathological condition except sclerosis of the vessels Looking through our post-mortem registers I find in the last ten years 12 necropsies on patients dead from diabetes. In seven of these the pancreas was noted to be small, in four it was distinctly fibrous to the naked eye; in only one case did it appear even macroscopically to be absolutely normal. The microscopical appearances are unfortunately not recorded in the notes.

The difficulty of which I am most conscious in endeavouring to establish a connexion between the pancreas and diabetes is not that of finding pancreatic lesions in cases of diabetes but rather the fact that quite as severe lesions may occur in cases in which there has been no diabetes; for the pancreatic cirrhosis in two at least of my seven cases was only moderately extensive, while I have found very advanced fibrosis apart from diabetes. At the same time diabetes is the condition with which pancreatic disease would appear to be most frequently associated, for whereas five out of seven diabetics[3] exhibited lesions the figures for other diseases are:—

Arterio-sclerosis,	6	cases of pancreatic disease out of	11	cases examined.
Carcinoma,	4	„ „ „ „	16	„ „
Tuberculosis,	3	„ „ „ „	14	„ „
Aneurysm of the aorta,	1	„ „ „ „	3	„ „
Heart-disease	2	„ „ „ „	9	„ „

All authorities appear to be agreed that there are a certain number of cases of diabetes mellitus in which no alterations are discoverable in the pancreas. They differ as to the proportion of such cases. On the other hand, many cases exist in which the pancreas is the only organ in the body which exhibits any sign of disease. The attempt to reconcile these facts presents a difficult problem. Several answers may, however, be given. In the first place, the suggestion has been made that it is not the glandular cells lining the acini of the pancreas and forming the main bulk of the organ by which the sugar-regulating function is carried on

---

[illegible] recorded in the post-mortem notes. Moderate degrees of this condition would probably escape record.

but certain special cells of different formation which are scattered throughout it in small distinct masses. These are the "cell islands" named after Langerhans who first described them. They appear to be formed from the same rudiment as the rest of the pancreas and are epithelial in nature. According to the accepted view they are at first connected with the ducts of the gland and this condition seems to persist for some little time after birth, as Opie has depicted a small duct entering an island of Langerhans in a case of congenital syphilitic pancreatitis. In adult life, apparently, this connexion with the ducts becomes obliterated and the islands remain as small groups of polygonal cells surrounded by a fine capsule which separates them from the surrounding acini. This separation does not appear, however, to be absolute, as it is possible to see islands here and there in which the cells are apparently continuous with the cells of the acini without any intervening fibrous tissue. These groups of cells are richly supplied with blood and are penetrated by a network of capillaries. They are scattered throughout the pancreas, but are considerably more numerous towards the tail of the gland. In stained specimens of pancreas the protoplasm of the cells forming these islands seems usually to take on a slightly different colour or a different depth of tint from that of the acinar cells, suggesting a slightly different chemical composition and therefore a different function, but the staining of the glandular cells is not constant and not much weight can be attached to such an observation. The general appearance of the islands of Langerhans thus somewhat resembles that of the glomeruli of the kidney, and they have been called by Kühne and Lea "pancreatic glomeruli." They differ, however, from the renal glomeruli not only in their irregularity of size and shape but also in that they have no connexion with the ducts of the organ, and hence their condition resembles rather that of a ductless gland, such as the thyroid or the suprarenal body, especially in view of their rich vascular supply. It has therefore been suggested that these cells are the source of the internal secretion of the pancreas. The idea was first mooted by Laguesse in 1895 and was adopted by Schaefer. It has since been supported by Opie and many others who have brought forward cases apparently pointing to a connexion between disease of the islands of Langerhans and diabetes. It may be of interest to mention that attempts have recently been made to connect the hypothetical internal secretion of the testis with certain special cells found in the organ, lying separate from the spermogenic cells of the tubules. If this hypothesis be proved true it will afford some support to the similar suggestion in the case of the pancreas; but the reality of this source of internal secretion is equally far from actual demonstration in the case of both organs.

It has been found that in diseases and injuries to the pancreas the islands of Langerhans often escape while the glandular cells are destroyed. Thus in experimental ligature of the ducts the pancreas appears to be converted into a mass of fibrous tissue, but the islands can often be discovered lying among the new tissue uninjured. This is probably owing to their lack of connexion with the duct-system of the organ; and it is possible to explain in this way the failure to produce diabetes which has been observed after ligature of the ducts or injection of them with tarry materials. Similarly, in some cases of inflammation of the pancreas the islands are said to escape the destruction which affects the acinar cells. In addition to this negative evidence tending to show the persistence of the islands of Langerhans in cases of apparent destruction of the pancreas in which diabetes does not occur, there are brought forward cases in which lesions of these structures have coincided with the existence of diabetes. A peculiar hyaline degeneration of the islands of Langerhans was described by Professor R. Saundby in his Bradshaw Lectures in 1890 and Opie has brought forward cases definitely connecting the condition with diabetes. In his first case, it is true, the degeneration was not confined to the islands but invaded some of the other portions of the gland; but in a later communication he recorded an instance in which this affection was the only visible lesion in a case of diabetes, the islands being apparently picked out by the degeneration and the rest of the pancreas remaining normal. Ssobolew found that in 18 cases of ordinary pancreatic atrophy in which there was no diabetes the islands of Langerhans were quite unaltered, whereas among 15 cases of diabetes there was recognisable alteration in these structures in
13 instances. Opie points out that in cases of coars
of the pancreas the islands are not generally
whereas in the fine variety of fibrosis of the
the new tissue tends to invade the islands and so
diabetes. Schmidt has seen a case of diabetes i
there was acute inflammation of the islands of Lan
with only a few similar foci in the rest of the panc
points out, however, that in this case—a child, a
years, who was passing 6·8 per cent. of sugar in the
the diabetes must have lasted longer than the infla
of the islands. Yet it is difficult to imagine a
inflammation which could pick out these structu
spare the rest of the pancreas. Seeing that the isl
shut off from the ducts of the gland no irritant cou
them from this source; it is only through the bloo
or lymphatics that it could be brought to them, a
equally supply the rest of the organ. It seems, t
permissible to question whether there was not in th
preceding lesion of the islands which rendered t
ceptible to some irritant which was not capable of
the glandular cells or whether the existence of dege
in these structures may have given rise to irritating
which caused accumulation of inflammatory cell
their capsules. Schmidt quotes two cases of
associated with pancreatic calculi in which the
appeared normal. In eight cases out of 23 of dia
could find no pathological change at all in the p
Weichselbaum and Stangl describe four possible c
of the islands which may be met with in diabe
diminution in size or number; (2) vacuolisation; (3)
and (4) induration or hyaline degeneration. The
affections of the islands present in every one of th
of diabetes. Gutmann out of 14 cases of diabet
changes in the islands in four; in six there was at
the pancreas as a whole, similar to that descri
Hansemann; in two cases no changes at all could
covered. In three of my seven cases of diabetes the
of Langerhans appeared to be greatly reduced in
It seems possible that they undergo fatty degenera
so disappear, as the distribution of the fatty patche
in such pancreases corresponds somewhat with tha
islands in normal glands. In three of my cas
appeared quite normal. In the arterio-sclerotic c
viously mentioned they appeared to be atrophic, the
themselves being vacuolated owing to disappearance
of the cells.

The most remarkable statistics on disease
structures in diabetes are those given by Lancerea
states that out of 167 collected cases no less than 130
alterations in the islands. Such results are very
and if confirmed by others will go far to prove the c
between these structures and diabetes. Experiment
islands alone is almost impossible. Lewaschew sta
by carbohydrate feeding and the injection of pil
many of the acini of the pancreas may be conver
islands, but Opie repeated the experiments and wa
to confirm these results. Herter and Richards st
injection of suprarenal extract causes granular dege
of the cells of the islands. It has been suggested
islands are immature acini waiting to be conver
mature glandular cells, but there appears to be no
in the islands in a fragment of the pancreas left behi
the rest is removed, so that they do not seem ca
giving rise to new acini. On the other hand, Schmi
that in some cases of fibrosis the islands are incr
number and size and he believes that they may be fo
of secretory tissue. He speaks of cases in which wh
of the pancreas are converted into cells resembling
the islands. I have myself noticed that in many ins
curious change is found in large areas of the gland,
being no longer arranged in acini around central sp
lying apparently closely packed side by side with
definite structural arrangement. As to what the
the change may be I have no suggestion to
the condition was met with in cases in whic
parts of the gland seemed quite normal, while t
in the altered portions stained in a manner
to healthy cells. There does not seem, however,
evidence upon which to consider these altered
of the pancreas to be converted into a new f
of "islands" and it seems probable that t
dition is a post-mortem change. I have, howev
portions of pancreas in which the islands were so
as to form a large proportion of the tissue presen

the view of Schmidt that the islands are formed from the glandular acini I am inclined to agree, in view of the appearances presented in many cases. Not only are the islands quite irregular in shape and size but one sees islands in which the typical cells are surrounded by a ring of secreting cells; others, again, in which masses of these latter are inclosed within the insular cells, and others in which cells staining like ordinary glandular elements appear to form part of the island and to merge into its structure. Increase of the islands has been described in some cases of infective disease, but the number and size of these bodies vary so greatly in different specimens of pancreas without any ascertainable cause and also in different parts of the same pancreas that it is practically impossible to fix upon an average number or size which is to be considered normal and which shall serve as a standard of comparison.

Ssobolew found in one case of diabetes enormous enlargement of the islands ("struma of the islands"), so that some of them measured as much as 1·5 millimetres in diameter. He suggests that this represented either a compensatory hypertrophy to make up for the loss of others which had disappeared or a process of tumour-formation. [illegible] ent in some of the islands in [illegible] in the capillaries, not in the [illegible] of the degeneration would thus seem very similar to that of amyloid change which starts in the vessels and only injures the cells secondarily by pressure. In a specimen kindly given me by Dr. Salusbury Trevor, of St. George's Hospital, the hyaline portion of the islands also seemed in most cases to be formed of degenerated capillaries, but here and there hyaline areas seemed to be formed of degenerated cells. Hence it seems doubtful whether there are not several conditions included in this so-called hyaline degeneration. On the whole, it is impossible at present to say that the relation between the islands of Langerhans and diabetes has been established. Hansemann, who has made a careful study of the pancreas in diabetes, denies that there is any connexion. Opie's case does, indeed, at first sight appear to afford an *experimentum crucis*, but it is so far lacking in sufficient corroborative evidence to establish a general rule. I could not be certain of any special alteration of these structures in any of my cases—certainly quite as marked changes were present in non-diabetic subjects. On the other hand, Lancereaux's statistics are very striking. Further, it seems to be admitted that hyaline degeneration of the islands has scarcely ever been observed in any other disease than diabetes,[5] so that there appears to be some connexion between them. The possibility is not, however, excluded that in diabetes the degeneration of the islands may be a secondary phenomenon. Still, the suggestion of these structures as the source of the internal secretion of the pancreas is a tempting hypothesis and explains some facts hitherto difficult to understand. More investigation is necessary before the question can be regarded as settled.

Even granting the connexion of the islands of Langerhans rather than of the secretory cells of the pancreas with diabetes there remain some cases to be explained in which no alteration of any part of the pancreas can be discovered. With regard to these we have to remember that, as has already been mentioned, we are dependent for our diagnosis of diabetes [illegible] presence of sugar in the urine [illegible] criterion is liable to be fallaci[illegible]d that we at present include under the term diabetes cases of very different natures. Every clinician must be familiar with cases in which sugar is found in the urine of a patient who comes for treatment for some entirely different condition—cases in which the patient appears to suffer no inconvenience from his glycosuria and goes about his work as usual until diabetes is diagnosed on account of the discovery of sugar. It seems almost certain that many of these persons are the subjects of an entirely distinct condition from those acute cases in which thirst, increased appetite, and rapid wasting are such distressing features. It is with the latter type of case—*diabète maigre*—that Lancereaux would associate pancreatic affections. They seem, indeed, to constitute a class by themselves, worthy of recognition as a separate disease, to which we should limit the name of diabetes, classifying the others as various forms of glycosuria, in which the appearance of sugar in the urine is indeed often a prominent feature, but in which there does not exist that internal breaking down of the tissues into sugar characteristic of the graver disease.

But a second possible explanation has to be considered and that is the fact that we are not yet in a position to exclude the existence of disease in any organ because our present methods of examination do not reveal definite structural alteration. Although true functional disease as opposed to organic cannot exist, yet there are only too many conditions in which the perversion of function is all that we are able to recognise. Minute alterations in the molecular composition of the pancreas may be present in some instances which we cannot discover with the microscope.

Thirdly, we have to take into consideration the influence of the nervous supply of the pancreas. It is conceivable that although the cells themselves may be normal in structure, yet if they be acted upon by abnormal nervous stimulus they will give rise to different products or fail to produce any secretion at all. Of the effect of nervous influence upon the origin and [illegible] many proofs. In many cases [illegible] act upon the liver in a mar[illegible] puncture, thus causing the [illegible] into the blood. But in som[illegible] it may be that the internal secretion of the pancreas is affected. If there can occur, as is well known, a sudden *drying up of the salivary secretion as a result of fright* we can equally suppose a sudden cessation of the formation of an internal secretion. If a total alopecia may result from shock and persist subsequently—and cases of such an occurrence have been met with—the defect of pancreatic secretion may equally persist as a permanent lesion.

In connexion with the question of the relation of pancreatic disease to diabetes it may be of interest to consider how far the known causes of the former correspond with those responsible for the latter condition. I have already alluded to the fact that both diseases tend to occur towards the latter part of life, diabetes being usually first complained of after 40 years of age and pancreatic fibrosis also occurring with greater frequency after this period. The connexion of arterio-sclerosis with fibrosis of the pancreas is also recognised, and this degenerative state has been frequently noted in diabetics, in whom it is probably responsible for most of the cases of gangrene of the extremities which occur, as well as being one of the assigned causes of the onset of the disease. The association of gout with diabetes is not improbably due to this accompaniment of both conditions. Another cause of pancreatic fibrosis, *as already pointed out*, is syphilis, and this infection almost certainly plays an important part in the production of a certain proportion of cases of diabetes; in my series, as previously stated, it was a likely factor in 12½ per cent. *The most important* cause of pancreatic fibrosis is probably the entry of micro-organisms by the ducts from the duodenum. This has been proved experimentally to cause inflammation of the gland and subsequent scarring. A history of digestive disturbance is not uncommon in diabetic cases and a certain number seem to date from a definite attack of vomiting and diarrhœa. Such instances may perhaps be associated with pancreatitis from intestinal catarrh. It might also be suggested that the abdominal, and specially epigastric pain, to which I have alluded as so often complained of by these patients, may be connected with inflammation of the pancreas. The apparently infective cases of diabetes, such as those collected by Hutinet, may [illegible]aps be attributed to this method of causation, although [illegible] observer *suggests* that the infective agent in such [illegible]nces acts by *producing* a condition of arterio sclerosis. [illegible]ally, the frequency of a history of alcoholism in [illegible]tic cases fits in well with th[illegible] [illegible]ausation. As cirrhosis of t[illegible] [illegible] so fibrosis of the pancreas [illegible] many instances to its action. A[illegible] influences—and some "family" cases are attributed by Hutinet to infection—there is a considerable degree of correspondence between the causes of acquired diabetes, if it may so be called, and those of pancreatic affections.

In view of the difficulty which at present exists in explaining all cases of diabetes on the basis of pancreatic defect various suggestions have been made in the direction of a joint action of this organ with some other in the regulation of sugar metabolism. In looking round for some organ to which to assign the complementary rôle attention naturally fell first upon the liver. As indicating a connexion between the two it is pointed out that removal of the pancreas causes disappearance, or, at all events, diminution, of the glycogen in the liver, only traces being left a few days after the operation, even when the animals receive a rich carbohydrate diet. On the other hand, injection of pancreatic extract into animals has an exactly similar effect, the diminution in the glycogen being proportional to the amount of material injected (Tyson). Again, if blood is caused to pass through the liver it is found that a certain proportion of the glycogen contained in the latter is removed in the process. If, however, the blood is first caused to pass through the pancreas less sugar is extracted in its subsequent journey through the liver (Lépine). On the other hand, Hirsch found that an emulsion of hepatic tissue destroyed more sugar if an extract of pancreas was added to it. These results appear contradictory and at present inexplicable. Ohlmacher states that the islands of Langerhans show hypertrophy in cases of hepatic disease and regards this as a compensatory hypertrophy to make up for hepatic defect. An elaborate hypothesis as to the interaction of the liver and pancreas in the process of sugar-regulation was formulated by Chauveau and Kauffmann. According to these authors there exists in the medulla a special centre which restrains the formation of sugar in the body and this centre is stimulated by the pancreas. On the other hand, there is a centre in the cervical cord which stimulates the formation of sugar and the pancreas depresses the activity of this latter. These centres together regulate the sugar-forming process which is actually effected by the liver. This hypothesis cannot be said to have proved fruitful or helpful in investigating the problems of diabetes.

In connexion with the question of a possible interaction between the liver and the pancreas allusion may be made to the curious condition known as hæmochromatosis or bronzed diabetes. This affection was first described by Hanot and Chauffard in 1862 and since then a fair number of cases have been recorded, though it remains a very rare disease. The following case which I had the opportunity of observing was apparently an instance of this affection. A man, aged 60 years, was admitted to Charing Cross Hospital under the care of Dr. Bruce, on June 7th, 1898, complaining of severe pain across the abdomen. He was almost certainly of alcoholic habits but denied that he had suffered from any serious illness in his previous life. He had been losing weight for about a year previously to admission. For the last fortnight he had suffered from loss of appetite and a feeling of depression and he had noticed some swelling of his legs and scrotum. Finally, he had been seized with excruciating abdominal pain, of sudden onset, which had "doubled him up" and caused him to come to the hospital. When seen he was still in great pain and was sweating profusely. He was slightly jaundiced. His abdomen was full and there was tenderness over the right hypochondriac region. The liver was felt to be enlarged. His temperature on admission was 102° F. It fell in the course of the next few days and the pain diminished, but the general condition remained the same for some time. On June 14th sugar was noticed to be present in his urine and by the 20th it had reached a large amount. Then it diminished and on the 22nd and 23rd was entirely absent. On the 24th there was 8 per cent. present and on the 25th there was none at all. Subsequently the sugar reappeared and remained constantly present till his death. He improved greatly in his general condition for the first four weeks of his stay in hospital and was on the point of being discharged (July 5th) relieved when he developed erysipelas of the face which proved fatal on July 13th. At the necropsy the pancreas was found to be of the enormous size already recorded (weighing one pound); the liver was greatly enlarged, weighing four pounds two ounces, and was the seat of a finely-distributed cirrhosis. There was a considerable deposit of dark pigment in the fibrous tissue of the organ and in the peripheral zone of the lobules. There was no other discoverable disease nor were other organs visibly pigmented. The pancreas [illegible] free from pigment.

The three classical features of hæmochromatosis are glycosuria, hypertrophic cirrhosis of the liver, and pigmentation of the skin and internal organs. Of the viscera the liver presents the greatest degree of pigmentation, but the cells of the pancreas and of the salivary glands and those lining their ducts are also affected; and according to Rabé the lungs are also the seat of pigmentation. The pigment is supposed to arise by a breaking-up of the blood-corpuscles and the pigmentation of the organs takes place in the process of eliminating the products of the broken-down hæmoglobin. Two separate pigments have been isolated, a brown substance containing iron, said by Auscher and Lapicque to be a hydrate of iron; and a black one free from iron. Neither cirrhosis of the liver nor glycosuria is, apparently, invariably present in this disease, nor is a condition of fibrosis of the pancreas always found. The relation of the condition to glycosuria presents, therefore, a very interesting problem. Since glycæmia (as evidenced by glycosuria) is not invariably present it cannot be, as suggested by Hanot and Chauffard, that the existence of sugar in the blood is the cause of the breaking up of the blood corpuscles—an idea improbable in itself, since in most grave cases of diabetes, in which there is a large quantity of sugar in the blood, there is no evidence of pigmentation. The glycosuria of bronzed diabetes seems, indeed, to be a late occurrence in many cases. The peculiar condition of intermittent glycosuria which was found in the case above recorded has not, so far as I know, been previously noticed in association with this condition; but it seems that the disease is susceptible of cure, as in a case recorded by Murri; in this, curiously enough, there were no signs of cirrhosis of the liver; the pigmentation of the skin and the glycosuria disappeared under treatment. It is tempting to suggest that the presence of sugar in the urine in those cases—at all events, in the early stages—is due to disturbance of the liver and is a glycosuria not a diabetes. More probably, perhaps, we are in the presence of a functional disturbance of the pancreas. In some cases, as in the one which I have recorded, the pancreas undergoes serious organic changes towards the end of the illness; and if the affection of this organ is sufficiently grave, true diabetes ensues. The cells of the pancreas did not appear to have suffered any structural change from the fibrosis in Dr. Bruce's case; this may, perhaps, account for the glycosuria being intermittent and not continuous, but it might be anticipated that if the fibrous tissue subsequently contracted, or the cirrhosis became more pronounced, permanent interference with the functions of the organ would ensue and lasting diabetes—if this be really connected with pancreatic insufficiency—follow. What may be the source of the poison which causes the destruction of the blood-corpuscles there are apparently no data to help us to determine. The existence of a biliary cirrhosis of the liver and the pigmentation of the abdominal organs to a greater degree than those elsewhere seem to point to a source in the alimentary canal, and the cirrhosis of the pancreas would seem to confirm this conjecture, since, as has been previously mentioned, infection passing along its duct appears to be the usual cause of fibrosis of this gland.

ABSTRACT OF

The Hunterian Lectures

ON

THE DISSEMINATION OF MAMMARY CARCINOMA.

Delivered before the Royal College of Surgeons of England on [illegible] March 13th, 15th, and 17th, 1905,

BY W. SAMPSON HANDLEY, M.S., M.D. LOND., F.R.C.S. ENG.,

HUNTERIAN PROFESSOR; SURGEON TO OUT-PATIENTS, SAMARITAN FREE HOSPITAL; "RICHARD HOLLINS" CANCER RESEARCH SCHOLAR, THE MIDDLESEX HOSPITAL.

LECTURE II.[1]

Delivered on March 15th.

MR. PRESIDENT AND GENTLEMEN,—In my first lecture I laid before you the clinical and statistical evidence for my belief that cancer of the breast spreads in the parietes centrifugally and by continuity and that it probably spreads primarily in the plane of the deep fascia where the principal parietal lymphatic plexus is situated by actually growing along (permeating) the vessels of this plexus. The object of this lecture is to place before you the histological proofs for the theory thus provisionally outlined. To obtain these proofs it was necessary to examine the parietal tissues over a wide area, preferably by means of long radial sections extending in one or more directions from the primary neoplasm. This has been done with some completeness in three cases and partially in two others. I would like in passing to express the opinion that there is much yet to be done in morbid histology by the application of microscopic methods on a macroscopic scale. Each of the strips examined, which varied in length from two to about 18 inches and included skin, fat, fascia, and a layer of the underlying muscle, was divided by transverse cuts into a series of blocks of tissue and the proximal end of each block was carefully marked. The blocks were transferred in order to numbered bottles and sectioned by the paraffin method. The corresponding longitudinal series of sections gave a view of the whole length of the original strip. In order to examine the strip in its breadth as well a series of sections was in one of the cases mounted from each block. From this case about 500 sections were prepared and examined. I propose first to describe somewhat fully a case in which the various processes were most easily traceable, next to give a general description of those processes, and lastly, by a recital of the other cases, to show how, under widely divergent appearances, the working of these processes may be traced.

CASE 1.—The patient was aged 66 years. On the thorax in the region of the right breast was an ulcerated tumour as large as an orange. It was surrounded by isolated hard nodules which extended to the right axilla, where there was a mass of growth causing œdema of the arm. Similar nodules were present in the left breast and there were a few small ones on the skin between the breasts. Elsewhere the skin was free from nodules. There were no enlarged glands in the right axilla. The right supraclavicular glands were palpable. The sternum and three of the right ribs were infiltrated and the growth had penetrated to the right pleura which showed numerous nodules, especially on its parietal portion. The right lung presented a few nodules; the left one also but to a less extent. The liver presented several superficial nodules on its surface near the round ligament. The other abdominal organs were normal. The parietal strip examined was a median ventral one, extending from 25 millimetres below the suprasternal notch to a point 60 millimetres above the umbilicus. A slice of this strip three millimetres thick was stained and rendered translucent by a method which I have elsewhere described.[2] At the level of the breast the subcutaneous tissues showed dense nodular infiltration with growth and there only could invasion of the skin be seen. The underlying pectoralis was partially infiltrated by growth. As the strip was traced downwards, a line of about four nodules was seen lying upon the upper two inches of the anterior layer of the rectus sheath. The skin over these nodules appeared normal. In its upper part the strip was defective, and owing to the absence from it of fascia and muscle the upward course of the growth could not be traced. Examination with the naked eye thus showed that the growth was spreading along the plane of the deep fascia, not along the skin, and that the growth had spread downwards beyond the lower limit of the pectoral fascia and over the abdominal wall. In order to determine the nature and extent of the fascial spread a parallel strip was microscopically examined along its whole length.

Appearances seen in a radial section extending upwards from just above the umbilicus to the level of the primary growth.—The microscopic growing edge of the cancer reached to a point about one and a half inches below the ensiform cartilage. Below this point the tissues were proved to be entirely free from growth down to the lower end of the strip, while above it they showed foci of growth at short and fairly regular intervals, varying from one millimetre or less up to five millimetres. The lower limit of the pectoral fascia had not in any way checked the downward extension of the growth. At one point the cancer had penetrated the anterior layer of the rectus sheath nearly to its deep surface. Had the section passed through the linea alba at the same level cancer cells would doubtless have been seen in ominous proximity to the subperitoneal fat and the peritoneum (see Lecture III.). For a breadth of over 30 millimetres the microscopic margin of the carcinoma lay exclusively in the plane where the deep fascia joined the overlying fat. Clearly, therefore, it was extending primarily along this layer. At the extreme growing margin the cancerous foci took the form of cross sections of lymphatic vessels belonging to the deep fascial lymphatic plexus filled but not distended by the growth of cancer along them. The cancer cells were in an active condition. There was no sign of inflammatory reaction to the cancerous invasion. Higher up—i.e., nearer to the primary growth—the lymphatics showed increasing distension by the growing cancer cells, which themselves were undergoing degeneration as the result of the increased pressure produced by their proliferation. Around the invaded lymphatics were seen collections of round cells. Still higher up were seen spaces containing cancer cells and a few red blood corpuscles. It will be shown later that these spaces were formed by the rupture of the distended lymphatics. Still higher cancer seemed to have almost disappeared from the deep fascia, but on close examination permeated and ruptured lymphatics were seen in process of obliteration by an inflammatory reaction which ended in the formation of fibrous tissue. The slender cylinders of cancer cells were finally strangled by the contracting fibrous tissue. Here also for the first time the adjoining layers, the skin and muscle, showed commencing nodular invasion. As the primary growth was approached the deposits became more massive and numerous. In this region the macroscopic nodules appeared isolated one from the other and the process of permeation could not clearly be made out.

Before describing the other cases I have examined I propose to anticipate some of the evidence and to give a general description of the pathological processes seen in the parietal spread of cancer of the breast.

PERMEATION AND ITS SEQUELS.

The growth of cancer along lymphatic vessels is, no doubt, simply the result of that same tendency to take the direction of least resistance, which on the surface of the body manifests itself in fungation. By preference the process seems to traverse vessels of not less than 40 or 50 μ in diameter, avoiding for a time those of smaller calibre and therefore of higher resistance. The trunk lymphatics also, as Stiles's researches have shown, remain free from growth until a late period, but for a different reason. In them the lymph stream is strong enough to sweep away as emboli any cancer cells which gain an entrance until, in a late stage, their outlet is dammed by growth in the glands or by external pressure. This, no doubt, is the reason why cancer of the thoracic duct is so rare. Nevertheless, when cancer of the thoracic duct does occur, the duct and its tributaries are so obviously converted into solid cords of growth[3] that the process of permeation can be followed by the naked eye. When the tissues are transparent, as is the case with the thin pleura and peritoneum, permeation can be seen without the aid of the microscope even in very minute lymphatics. In less favourable situations—as, for instance, in the parietal tissues—permeation cannot be directly observed and has to be inferred from sections. A permeated lymphatic plexus in vertical section would appear as a series of dots at intervals corresponding to the diameter of its meshes, each dot being a section of a cancer-filled lymphatic. The appearances in the radial section just described must, therefore, indicate permeation of the fascial lymphatic plexus.

---

[1] An abstract of Lecture I. was published in THE LANCET of April 8th, 1905, p. 909.

[2] Archives of the Middlesex Hospital, vol. iii., 1904.

One of the main difficulties in the acceptance of the permeation theory of dissemination is that microscopic evidence of it is so often wanting. But the reason of this is not far to seek. I find that a lymphatic along which cancer has grown does not persist indefinitely in that condition until the death of the patient affords an opportunity for its examination. A series of changes occurs in the permeated lymphatic which usually ends in its destruction. I shall refer to this process as perilymphatic fibrosis.

[The lecturer here showed a number of photo-micrographs illustrating the various stages of permeation and perilymphatic fibrosis, which will appear in the forthcoming volume of the "Archives of the Middlesex Hospital."]

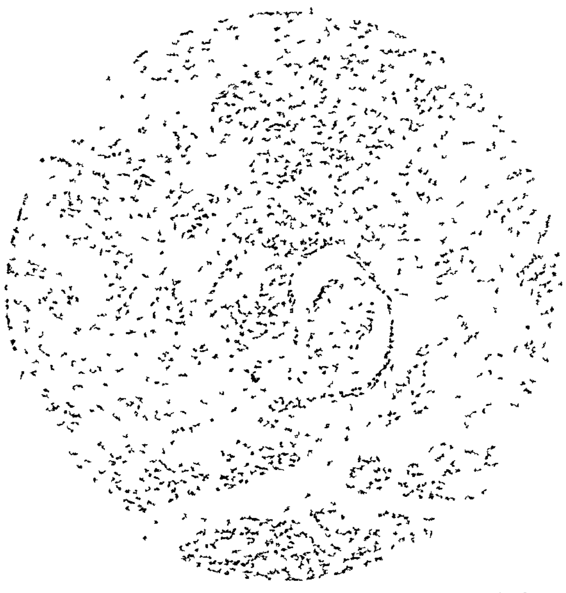
PERILYMPHATIC FIBROSIS.

It has already been stated that while cancer cells in blood cause clotting, cancer cells in lymph excite no such thrombotic reaction. Nor in the tissues round a permeated lymphatic is there at first any sign of reaction. Instead of being filled by lymph the lymphatic is filled by a cylinder of cancer cells but no other changes are visible. Soon, however, owing to the elasticity of the lymphatic and to the continued proliferation of the cancer cells within it the vessel is distended to several times its normal diameter. This distension is followed by a process of inflammatory fibrosis around the invaded lymphatic, analogous to that which on a large scale follows the prolonged distension of a hollow viscus, such, for instance, as the gall-bladder or the Fallopian tube. The commencement of this process is heralded by the appearance of round cells, apparently emigrated leucocytes, in the perilymphatic tissues. By this time the cancer cells themselves have undergone certain changes due to the harmful pressure resulting from their own proliferation. These changes are most marked in the centre of the mass of cells. Often a single layer of well-preserved cells forms a gland-like lining within the lymphatic endothelium, while all the central cancer cells are swollen, hyaline, refractile, and have lost their tinctorial affinity. Although, owing to the elasticity of its wall, a lymphatic vessel is for a time simply stretched and distended by the mass of cancer cells its powers of resistance are not unlimited. Sooner or later the permeated lymphatic ruptures (see Figure) and the cancer cells within it are set free to invade the surrounding tissues. The rupture frequently causes slight traumatic hæmorrhage into the space inclosing the cancer cells, which are now contained on one side by the endothelium of the ruptured lymphatic, and on the other side by a false capsule formed by the perilymphatic tissues.

At first sight it would appear that all obstacles to the interstitial spread of cancer in the perilymphatic tissues are now removed. But for two reasons this is not the case. In the first place, the cancer cells thus set free are frequently degenerate and unviable as the result of the pressure to which they have been subjected. In the second place, the rupture of a permeated lymphatic greatly intensifies the inflammatory reaction which was already present in the perilymphatic tissues. Round cells collect in large numbers around the liberated group of cancer cells and infiltrate its periphery. Round-celled infiltration is followed by the formation of granulation tissue and by the appearance of newly formed capillaries. A definite capsule of young fibrous tissue is soon seen inclosing the mass of cancer cells, and although the latter may for a time increase and multiply within their fibrous capsule, they are ultimately strangled by its contraction or destroyed by phagocytosis. Finally the permeated lymphatic is replaced by a slender thread of fibrous tissue not clearly distinguishable from a nerve except by special methods of staining. Perilymphatic fibrosis is obviously a curative process, but unfortunately, from this point of view, it has certain defects.

THE FORMATION OF NODULES.

It has been stated that at first permeation spreads only along the lymphatics of medium size. But in its later stages, owing to hyper-distension by cancer cells and to contraction of the perilymphatic fibrous capsule, the pressure within the permeated lymphatic is increased to such an extent that cancer cells are by this pressure and by their own proliferative power forced in a continuous line alor the smaller branch lymphatics. Each of these bran lymphatics takes origin from a bundle of lymphat capillaries which are in their turn invaded. In favourab



The illustration shows the rupture of a permeated and distended intramuscular lymphatic. Slight hæmorrhage has in consequence occurred and there is much round-celled infiltration around the rupture Near to the lymphatic are a normal artery and vein. The extension of permeation along the small tributaries of the ruptured lymphatic can be seen.

circumstances cancer cells still viable may in this way rea the extreme periphery of the lymphatic system. The wa of the lymphatic capillaries consists simply of a layer endothelium and can offer no effective resistance to intern pressure. Consequently, before inflammatory reaction ca occur there is interstitial invasion of the tissues and a loca ised nodule is formed, the limits of which correspond first, according to my observations, with those of tl capillary area into which permeation has extended. Pe meation of the smallest lymphatics is best seen in muscl At first lines of cancer cells are seen running betwe normal muscle fibres. Later the muscle fibres themselv may be seen occupied by cancer cells, while the permeat lymphatics have been replaced by fibrous bands. Of cours this is not the only way in which nodules may be forme Along the course of a medium-sized lymphatic, for instanc fibrosis may fail, if only at isolated points, and macroscop nodules may in consequence be formed. Not infrequentl such nodules are seen upon the deep fascia.

THE LATENT PERIOD OF THE REACTION TO PERMEATIO

Since a curative process of perilymphatic fibrosis is o of the results of permeation, the latter process might co ceivably thereby be arrested. And perhaps this does som times happen when the reproductive power of the canc cells is relatively small or when they cohere strong together. But since perilymphatic fibrosis only occurs in the late stage of permeation, it is usually absent at the microscopic growing edge of the carcinoma, which continues to advance. [illegible] keep always just [illegible] action. Dr. W. S. [illegible] process of stroma formation fails in a similar way to check the interstitial advance of a primary carcinoma, because it is absent at the actual infiltrating edge.

---

CONTINUITY OF THE SECONDARY DEPOSITS WITH THE PRIMARY GROWTH.

It appears that the parietal metastases of cancer of the breast, however remotely [illegible] with the primary growth. [illegible] continuity is destroyed [illegible] fibrosis, which obliterates the permeated lymphatics that originally formed the lines of communication. Probably metastases in the lymphatic glands are the only parietal metastases which originate from lymphatic embolism.

THE ZONAL ARRANGEMENT OF MAMMARY CARCINOMA IN THE PARIETES.

Although all the parietal secondary nodules may be regarded as outlying portions of the primary growth it is convenient to retain the term "primary growth" for the region of interstitial infiltration around the original focus. Beyond the boundary of this region three distinct zones may more or less clearly be recognised. In absolute and relative extent they vary enormously in different cases, and of course in different stages of the same case. Those zones are as follows.

(*a*) *Zone of isolated nodules.*—This zone immediately surrounds the primary growth. In it isolated or confluent nodules are present in the various layers of the parietes. The intervening permeated lymphatics have partially or completely been destroyed by perilymphatic fibrosis.

(*b*) *Zone of active perilymphatic fibrosis.*—In this zone permeated lymphatics are recognisable in the deep fascia undergoing the [illegible] lules are commencing [illegible] this zone the proces[illegible] least resistance, is usually found only in the deep fascia, where the main lymphatic plexus is situated.

(*c*) *Zone of fascial permeation.*—This is subdivisible into a proximal and a peripheral zone. In the proximal portion of this zone the permeated and distended lymphatics of the deep fascia are surrounded by perivascular collections of leucocytes. Permeation has not to any extent invaded the small tributaries of the fascial plexus and cancer is found only in the deep fascia and in the immediately overlying subcutaneous fat. In the peripheral portion of the zone which forms the microscopic growing edge the permeated fascial lymphatics have not yet been distended by the cancer cells within them and no excess of leucocytes is present either around the permeated lymphatics or in the blood-vessels near them. Inflammatory reaction to the cancerous invasion is thus entirely absent at the growing margin.

Case 1 was an especially favourable one for the microscopic study of dissemination in the parietes. Permeation was proceeding fairly rapidly and hence the zone in which it occurred was a wide and well-marked one. Visceral metastases had killed the patient before the area of extension had become unmanageably large. In the next case I shall place before you the process of permeation was slow and the zone of permeation consequently very narrow. The survival of the patient for a long period allowed the zones of isolated nodules and of perilymphatic fibrosis to reach a considerable width. The later stages of fibrosis were consequently better seen than in Case 1.

CASE 2.—The patient was aged 73 years. The right side of the chest presented a cancerous ulcer as large as a man's hand, extending from the second to the sixth rib, to the anterior fold of the axilla, and to the margin of the sternum. There were metastases in the right and the left axillary and in the right supraclavicular glands, and in the left breast. Beneath the primary growth the ribs and the right pleura were infiltrated. Posteriorly there were some small scattered growths on the parietal pleura, especially in its lower part. In the abdominal cavity there was a malignant deposit on the anterior border of the right lobe of the liver and one portal gland was cancerous. Two radial strips were examined running in different directions from the edge of the ulcerated growth. To the naked eye the proximal portion of the strips presented a line of confluent nodules along the junction of the dermis with the subcutaneous fat. Further on the nodules became smaller, with [illegible] al skin. At the distal [illegible] Along the whole len[illegible] esent in the plane of the deep fascia. So far the evidence was strongly in favour of the accepted view that cancer of the breast frequently spreads along the skin in the plane of the (hypothetical) deep cutaneous plexus. Histological examination of the strips showed the following points:—

Strip A, extending for 90 millimetres from the ulcerated edge down the right arm.—The strip was divided into six blocks, four of which were cut in series. About 250 sections from the strip were examined.

Skin.—Nodular and interstitial invasion was present more or less continuously but with diminishing intensity along the proximal 76 millimetres of the strip. Beyond this point there were two minute isolated nodules at the deep aspect of the dermis. The more remote of these two nodules was situated 84 millimetres along the strip one millimetre beyond the furthest point of invasion of the deep fascia. An oblique fibrous septum containing permeated lymphatics connected this nodule with a point on the deep fascia *proximal* to the narrow zone of fascial permeation now to be described.

Deep fascia.—In the proximal 45 millimetres of its length the deep fascia was entirely free from cancer. Several fibrous areas (fibrosed lymphatics) were seen lying near blood-vessels. At 45·5 millimetres from the proximal end of the strip was an oval area of concentrically arranged fibrous tissue inclosing a few degenerate cancer cells. Beyond this point the strip was again free from cancer as far as 63·5 millimetres. Here was seen a lymphatic about 100μ in diameter, filled by cancer cells which had ruptured its walls at one point. In another section of the series the lymphatic was replaced by two smaller ones and had evidently bifurcated. We now come into the zone of permeation and cancerous lymphatics are seen at short intervals. At 72·5, 76, 77, 78, 79, 81, and 83 millimetres permeated lymphatics of gradually diminishing size were present upon the deep fascia. From 83 millimetres to the end of the strip the fascia was free from cancerous invasion. Thus the zone of fascial permeation was here about 11 millimetres wide.

Muscle.—Along the whole length of the strip the muscle had escaped invasion.

On the centrifugal hypothesis the appearances in any two radial sections of the parietal tissues around the primary growth should be approximately alike. Strip B will show us whether this is in fact the case.

Strip B, extending for 83 millimetres from the ulcerated edge downwards and backwards into the loin across the lower ribs and lumbar fascia.—The strip was divided into seven blocks, most of which were cut serially. Over 200 sections from the strip were examined.

Skin.—The appearances in the skin were similar to those found in Strip A. Cancerous invasion was present as far as a point 49 millimetres from the proximal end—i.e., for the same distance as in the deep fascia. From 0 to 36 millimetres the skin showed nodular or interstitial growth more or less continuously. From 36 to 49 millimetres only two minute skin nodules were seen and these were not present in all the sections taken from this particular block.

Deep fascia.—In Strip B two strong layers of fascia, separated by a thin layer of fat, were present over the muscles. Cancer foci were found chiefly on the more superficial of these layers. Cancer was first met with nine millimetres along the strip where a circular mass of nucleated fibrous tissue, inclosing in its meshes a few degenerate cancer cells, was found. It was about 300μ in diameter and lay at the point of junction of a fibrous septum with the deep fascia. Above this fibrous septum ran into the "tail" of a skin nodule. One millimetre further along the strip was a similar fibrous area, 600μ in diameter, containing a large number of degenerate cancer cells. Fibrosis was less advanced than at the preceding focus and a large number of round cells were still present in the organising fibrous tissue. At the other end of the series of sections derived from this particular block the same lymphatic was seen as a solid cord of fibrous tissue, only 300μ in diameter, containing newly-formed capillaries and including only a few ghosts of cancer

---

[4] Lazarus-Barlow: Text-book on General or Experimental Pathology, second edition, p. 515.

cells in the last stages of degeneration. Thus certain stages of perilymphatic fibrosis were traced *at different points along the length of the same lymphatic.* The two fascial foci of cancer just described were the only ones present along the proximal 25 millimetres of the strip. Beyond this point we leave the zone of perilymphatic fibrosis and enter that of permeation. Permeated lymphatics are now found at short intervals. They are present at 28, 29, 31, 35, 35·5, 38, 39, 43·5 millimetres, and inconstantly (in the series of sections from this block) at 49 millimetres. The zone of permeation at this point was thus about 21 millimetres wide. Distension and rupture of the permeated lymphatics are visible towards the proximal border of the zone, while towards its distal border the lymphatics become smaller, since they are filled but not yet distended by the cancer cells. From 49 millimetres to its termination 83 millimetres from the edge of the ulcerated growth all the layers of the parietes were entirely free from growth. In particular a series of sections taken from the block immediately beyond the microscopically determined growing edge was entirely free from cancer.

Muscle.—The muscle has escaped invasion except at one point 38 millimetres from the proximal end of the strip. Here a small permeated lymphatic can be traced in longitudinal section for a long way down into the muscle. Since the parietes here are quite thin cancer might thus invade the perirenal fat and reach the lumbar glands (*cf.* Lecture III.).

The outstanding fact which emerged from the comparison of those two radial sections of the parietes was that in their proximal portion permeated lymphatics had disappeared from the deep fascia and that further from the growth an advancing edge of fascial permeation was present. These two radii were taken in random directions from the primary neoplasm and there is no reason to doubt that radial sections in any other directions would have given similar results. If this be admitted the existence of an annular area of permeation surrounding the growth at some distance from its macroscopic edge must be taken as proved. Permeation was absent over a wide zone, intervening between the zone of permeation and the primary growth. But that permeation had been present in this region, and passing beyond it had given place to perilymphatic fibrosis, was conclusively shown at a few points where all the stages of the metamorphosis could be traced. In Case 2 the three zones so clearly seen in Case 1 are foreshortened and confused but still recognisable. Owing to the absence of nodule formation in the layers adjoining the deep fascia, the zone of active perilymphatic fibrosis is better seen than in Case 1. But the most important new link in the chain of evidence was that the various stages of perilymphatic fibrosis were shown not in different lymphatics but at successive points along the length of the same lymphatic.

One difficulty has still to be met. In some sections invasion of the skin had extended slightly beyond fascial invasion and it may be said that cancer was extending along the skin and only secondarily extending from the skin to the deep fascia. The explanation is simple. Some of the fibrous septa along which permeation extended to the skin from the zone of perilymphatic fibrosis ran obliquely in a distal direction to a point on the skin beyond the narrow advancing edge of fascial permeation which formed the true growing edge of the cancer.

[The lecturer next described the histological results derived from Cases 3 and 4. These cases, though less completely examined, confirmed in general outline and in some respects extended the conclusions reached from Cases 1 and 2. He continued:—]

We have now studied cases in which parietal extension was moderately rapid and cases in which it was slow. In the case now to be described parietal dissemination was very rapid and had reached an extreme degree.

CASE 5.—Six months before death the patient first noticed a lump in the left breast. Subcutaneous nodules soon appeared, at first near the breast. A fortnight before death they were scattered universally, though irregularly, over the whole body except upon the distal portions of the arms and upon the lower extremities. At death nodules were present on both thighs as far as six inches below the anterior superior spine of the ilium. In this case, therefore, the clinical evidence for centrifugal spread appeared conclusive and an increase in the size of the invasion circle was directly observed during the last fortnight of life. The histological characters of the growth were peculiar. Its cells were of moderate and uniform size with round and vesicular nuclei and displayed a marked tendency to vacuolation and degeneration. The growth was classified as an endothelioma. The following parietal strips were removed and examined histologically along their whole length: (1) from the right acromion down the right arm to a point six inches above the wrist; (2) a coronal strip of the scalp from the vertex to the ear; and (3) a median ventral strip from the chin to the pubes. In these strips numerous isolated nodules were found, on the one hand in the subcutaneous fat and on the other hand in the muscle. The deep fascia was nowhere found permeated but it presented at some points fibrous areas which were probably fibrosed lymphatics but which possibly represented nerves. The skin had almost everywhere escaped invasion. No sign of invasion of the blood-vessels was seen. It could be made out with some probability that the muscles were first invaded on their superficial aspect, for the two youngest muscular foci were situated just beneath the deep fascia. Even the negative results of this case, which cannot in any case outweigh the positive evidence of Cases 1 to 4, are best explained by the theory of permeation. I am not aware of any theory but that of permeation which will explain the centrifugal extension so clearly manifested in this case by the clinical evidence. And as regards the microscopical evidence, it is at least possible that the strips examined, long though they were, failed to pass beyond the zone of isolated nodules into the outlying zones of active fibrosis and of permeation.

Parietal Dissemination a Serpiginous Process.

The general resemblance between the mode of spread of cancer of the breast in the parietes and the mode of spread of certain annular and serpiginous forms of skin disease cannot escape notice. But the spreading ring of cancerous permeation usually leaves in its track here and there isolated nodular foci which give rise to macroscopic nodules. It is probable, however, that this is by no means invariably the case,—that perilymphatic fibrosis, while unable to overtake the spreading ring of fascial permeation, may be successful in preventing nodular invasion of the adjoining layers. Possibly, too, the ring of permeation might die out at some portion of its circumference and continue to advance only as the arc of a circle. In such cases years of apparent health might in the end be followed by recrudescence at some remote vulnerable point, towards which in the meantime the process of permeation had steadily been creeping in a latent and microscopic form. It appears to me that permeation thus affords a rational explanation of the unsolved mystery of late recurrence.

THE "CURE" OF CANCER.

BY EDMUND OWEN, F.R.C.S. ENG.,

SURGEON TO THE FRENCH HOSPITAL, AND CONSULTING SURGEON
TO ST. MARY'S HOSPITAL, LONDON.

IS a surgeon ever justified in claiming that he has *cured* a patient of cancer?

A surgeon may truly say that he has cured a person of a broken thigh-bone, or of an abscess in the hand, for by treatment he has relieved him of his trouble once and for all. But with cancer it is different. For a patient with cancer the surgeon may promise that he will "do" his "best"; but more than this he must not, cannot promise. And to "do his best" he makes a wide sweep of the growth with his knife, getting so far beyond it, indeed, that he may well hope and believe that, together with the tumour, he has taken in every cancer-germ. But, notwithstanding his wide sweep, he can never be sure that none of these germs had passed beyond it. And a cancer-germ adrift in the lymphatic stream is like a message thrown out to sea in a bottle: it may be found years afterwards—goodness only knows when or where.

In an almost pardonable wish to show forth the results of his operative-work in an attractive form, the surgeon is sometimes tempted to set up for himself a "time-limit," and then to say, "If after operation there is no sign of return of cancer in any part of the body within this period, I shall count the case as *cured.*" After all, this time-limit of his is but arbitrary. One surgeon may fix for himself a ten-years' limit; whilst another who is, perhaps, more sanguine, or who is possessed by a greater natural anxiety to show pleasant results, makes his a three-years' limit.

And if *three years*, why not *three months?* But could a surgeon who looks at facts, rather than at figures and fancies, regard the three-year group of operations-cases or even the ten-year group as *cures?* I think not. It may be much more than ten years before that little mass of drifting cancer-cells is, by chance, found cast up in an ovary or in the uterus. And if when the unwelcome discovery was made the *Table of Results* which counted that particular case amongst the *Cures* had not been already published, an important change in its appearance would have reluctantly to be made.

Far be it from me to write as one without hope with regard to the cure of cancer; but neither aspirations nor statistics can alter plain pathological facts. And it seems to me that just now Surgery (with, perhaps, a becoming wish to remove attention from her red-stained apron, and to show herself less unpleasing to the public eye) is growing a little too free in the use of the word *cure* in connexion with the treatment of cancer. Surgery should remain cold and unemotional, and, though full of hope, should not go in advance of facts. And one fact is this, that at present it is beyond her power to undertake to *cure* cancer—neither can *x*-rays nor Finsen's light, nor can any drug or nostrum taken internally or applied locally, do this. Treatment is, unfortunately, not the same thing as cure, and the most effectual treatment for cancer is still removal by the knife. Certainly for anything more serious than a small surface-growth, no measure is so trustworthy. And the great advantage which this method has over all others is that it enables the surgeon to take away also the neighbouring lymphatics, and the outlying lymphatic glands. It is by the greater freedom and thoroughness of modern methods of operating, that Surgery has of late made such great advances in the treatment of the disease. That she has advanced, and is still advancing, is beyond dispute.

And though Surgery is still unable to lay claim to curing cancer, operation, if done early and freely, and repeated again and again if need be, can, in certain cases, bring lasting relief. The following report serves as a good example of this ability:—

In May, 1876, Sir William (then Dr.) Broadbent sent to me a domestic servant with cancer of the right breast. And in doing so he asked me, if I thought fit, to try the effect upon the growth of injections of acetic acid—a method of treatment in which he had formerly been much interested. The patient, Mrs. ——, was 55 years old, a widow, who had never borne a child. She said that she had noticed the lump in the breast for about three months, and that for a long time before this she had been much troubled by feelings of pin-pricking there. The lump was very hard: there could be no mistake as to its nature. I very willingly carried out Dr. Broadbent's suggestion, making injections at six different times. But finding that the tumour was steadily getting larger, I freely removed the breast with the knife in the following July. After the operation I cut the tumour across: it was as if one were drawing the knife through an unripe pear.

Fifteen months later, namely, in October, 1877, she came up again because a hard lump of the size of a large walnut had grown upon the scar. This was freely removed by the knife, but very soon afterwards another growth appeared, which I dealt with in the same way in February, 1878 In December, 1879, she was again in trouble with the scar, so I once more operated by a clean sweep; and as at this time there were some enlarged glands in the arm-pit, I did a more thorough operation, clearing away all the axillary lymphatics. This was the last operation done upon her, and soon afterwards she asked me to fill up a schedule so that she might become a pensioner at the Royal Hospital for Incurables. This was rather more than a quarter of a century ago, and she has ever since been happily drawing her pension.

In answer to a letter from me, she wrote on March 24th, 1905, as follows: "You will be pleased to hear that I am wonderfully well and active, in my 84th year. Just now I am busy knitting night-socks for a kind lady."

If I kept statistics of operative work—a dangerous thing for some of us—I think that I should be almost tempted to claim this particular case as a cure of cancer by operation. And no one, I believe, would accuse me of undue haste in reporting the case or of arrogance in making the claim. I have other cheering cases which, were I a surgical statistician with a time-limit, I might be inclined to place with it But, as it is, I shall let Mrs. ——'s case stand by itself, and shall content myself with saying that in the other cases there is at present "no sign of return"—and this, in my opinion, is as much as a surgeon is ever justified in claiming as the best result of his treatment of cancer. For, unfortunately, the "cure" of cancer seems still to be as far off as ever.

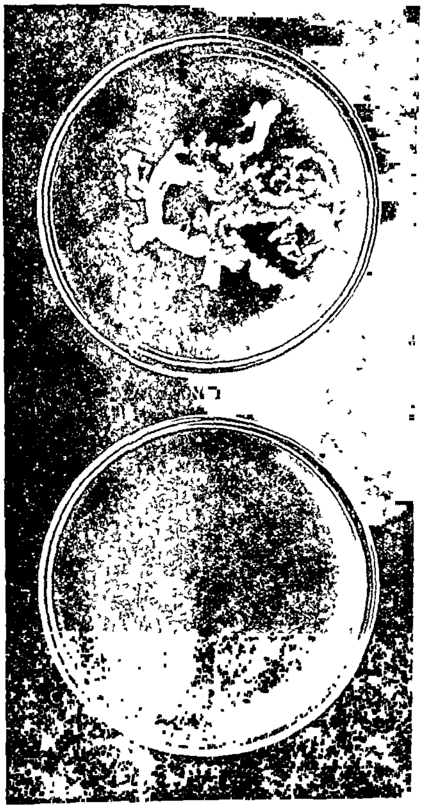
Great Cumberland place, W.

CYLLIN INHALANT.

By E. KLEIN, M.D., F.R.S.,

LECTURER ON ADVANCED BACTERIOLOGY AT ST. BARTHOLOMEW'S HOSPITAL.

CONSIDERING the importance attaching to the presence of micro-organisms such as the staphylococcus pyogenes aureus and the streptococcus pyogenes in the purulent contents of the bronchial branches in pulmonary tuberculosis it was interesting to ascertain whether the new drug termed "cyllin inhalant" (which is not to be confused with the ordinary cyllin) has any germicidal influence on the above microbes. Experiments were therefore made with the staphylococcus pyogenes aureus in the following manner. Two surface agar plates were infected in the same manner and at the same time from the same active culture. One of the plates was kept as a control, while the other was operated upon in a Bulloch chamber with the "cyllin inhalant" for ten minutes, after which period of time it was left in the closed chamber exposed to the residual cyllinised air for one hour. The plate was then taken out and placed with the control



The upper lip was much swollen. The child was feverish and fretful. The mother stated that the previous week "he could not see out of his right eye." On lifting the lip the upper incisors were seen to be necrotic, over the right lateral and central pus oozed freely into the mouth. Ethyl chloride was administered and these teeth were removed. The roots of these teeth were as dark as their crowns; each had at its apex a small abscess sac. Half the crowns of each tooth were gone. *No milk* had been given.

CASE 6.—The patient was a boy of dark complexion, aged one year and 11 months. He was thin and fretful. He was very restless and kept the mother awake at night. On examination the four upper incisors were carious to the gum line, also the first upper molar on each side was deeply carious. All these were removed. The child had been fed on bread-and-butter and tea, sometimes a little meat, but *no milk.*

Such cases are by no means rare. The early age of the patient, with the absence of proper nourishment, are the chief characteristics, with perhaps a voluntary statement on the mother's part that "the teeth came through decayed."

CASE 7. *Sinus in the mandible from a temporary tooth.*—The patient, a fair-haired child, aged three years and nine months, was admitted on Jan. 21st. She was very anæmic and had a discharge from the lower jaw. On examination the upper teeth were found to be all in good condition and free from caries. On the left side of the mandible were two carious molars; in connexion with the first was a small sinus on the gum from which pus was oozing. On the right side of the mandible there were no molar teeth; these had been removed two months before. There was considerable thickening of the bone and beneath the site of the second temporary molar outside the mandible was a sinus with a free discharge of pus. Inside there was also a small sinus on the gum from which pus was oozing. Chloroform was administered and the carious teeth on the left side were removed; on the right side a probe was passed through the jaw into the mouth; no necrosed bone or the remains of a tooth were felt. The mother stated that at 12 months the child had "large" glands beneath the jaw which were lanced. The child's ears were pierced at three years "to save her eyes." The father had been out of work since Christmas. The child's food consisted of condensed milk and water, tea, and bread-and-butter, but no *fresh milk* or *meat*. The external sinus was treated with boric lotion on lint. Mistura ferri perchloridi was prescribed. One pint of milk was ordered each day. The child was thus treated for four weeks. She was much better and had gained four pounds in weight. The mandible was almost normal, the swelling was gone, and there was very little discharge. On March 4th the face was much swollen. There was a free discharge of pus from the sinus externally and internally. The father was out of work and the child had no milk. A month later the child was quite well. The father had work, the child was having good food and plenty of milk. Both sinuses were healed and only an external scar remained. This case is an object lesson in *malnutrition.*

CASE 8. *Chorea.*—The patient, a girl of dark complexion, was admitted on March 19th, 1901. She had been ailing for four or five months. She had well-marked chorea. There were movements in the face, the hands, and the feet, chiefly on the right side; she could not sit still. She was very anæmic. The mother stated that the child had been under medical treatment since the commencement of the illness. She had never had rheumatism or bronchitis, but had complained of pains in her legs. For the past month she had been under the treatment of Dr. Soltau Fenwick, my colleague. The appetite was bad. On examination the patient had foul breath and several necrotic roots of temporary molars in the maxilla and the mandible. These were removed. On May 14th, though better, the patient would not sit still; the appetite was better. She had had toothache for two days. On examination the upper six-year molar was carious and the nerve was exposed. This was removed. On the 21st the patient was rather worse. The mouth was still in an unhealthy condition; the mucous membrane round the necks of the teeth was deeply congested; there was no ulceration. One teaspoonful of lime juice three times a day was ordered. On June 4th she was much better; the mouth was clean and healthy; there was little or no movement in the limbs now.

Chorea is generally associated with rheumatism. It is well known that the symptoms are more likely to arise in children of a neurotic type. The symptoms appear to lie dormant for a time and then to be set up by very trivial causes. Given a neurotic subject, any source of irritation may be cited as a contributory cause or as a means of keeping up the movements so typical of the disease. Though closely associated in its pathology with rheumatism this disorder appears to be the expression of a nervous system goaded to desperation by accumulated ills. Removal of one evil alone does not effect a cure. It is only as each one is sought out and removed that the symptoms disappear. That a fruitful source of irritation may be found in carious teeth is well illustrated by this case, one only of many.[2]

CASE 9. *Nervous affection of the mouth and the eyes.*—On April 16th, 1901, a fair-haired girl, nine years of age, was sent on to me by my colleague Dr. Fenwick, who had treated her with belladonna and bismuth. There were twitching of the eyes and mouth and a general restlessness of the body. The complaint was not chorea. The girl attended school regularly and was in the second standard. On examination the four upper temporary molars were found to be deeply carious. These were removed as she could not eat without pain. On the 23rd she was much better. A lower six-year molar was filled. The gums were deeply congested and purple round the necks of the upper and the lower incisors. The breath was foul. She was ordered oatmeal porridge for breakfast. A teaspoonful of lemon juice in water sweetened with a little sugar was given three times a day. On May 1st the patient was quite well. She had no nervous tremors; the gums were quite healthy and the breath was sweet.

CASE 10. *General malaise; nervous tremors.*—The patient was a boy, aged ten years and six months, and was very anæmic. He had been ailing for the past three months. He would wake up in the night in a fright, with nervous tremors. There was much discharge on the pillow. His diet was good—vegetables, bread and milk, and meat. On examination the boy had a clean tongue but foul breath. He had six carious temporary teeth and six carious permanent teeth. The four lower temporary molars were necrotic; in connexion with those on the left side were sinuses from which pus was oozing freely. These four teeth were removed and the permanent teeth were filled. Mistura ferri [illegible]. In a fort[illegible] ous tremo[illegible] is a

CA[illegible] gan fair-h[illegible] to swell three months previously. These were inflamed and suppurating three weeks since; they were opened and were still discharging. On examination there was a suppurating submaxillary gland on the right side. There were a necrotic second temporary molar and the necrotic roots of a six-year molar on the right side of the mandible. No other source of irritation could be found. The tonsils and the pharynx were normal. The tooth and the roots were removed. A fortnight later the wound in the neck had ceased to discharge and only a scar remained.

In this case there was no evidence to prove that this patient was the subject of tuberculosis but I may remind you that one of the commonest sites for tubercle to develop in such glands is about the neck and beneath the lower jaw in those lymphatics which drain the surfaces of the head and face, and in fact those parts most liable to irritation. Mr. Edmund Owen, in a paper he read before this society,[3] directed attention to the fact that septic infection of the glands beneath the jaw frequently takes place in children through carious teeth. In reading over that paper and the discussion which followed I was struck with the fact that his opinions were received with a considerable amount of scepticism; but I have seen so much of it among the children of the poor that in private as well as hospital practice I never hesitate to sacrifice a tooth where the evidence of glandular irritation is present. It may be transitory, disappearing, as in this case, when the site of infection has been removed, but it may be tuberculous and spreading to other glands infect the whole body.

I have not attempted to divide these cases into local and constitutional because at best it is an arbitrary selection depending upon the severity of the symptoms. Two factors in the production of systemic disease stand out with considerable prominence in these cases, factors which, if I may say so, "play into each other's hands"—*defective dentition* and *malnutrition.*

---

[2] Diseases of Children's Teeth, p. 156 et seq.

[3] Transactions of the Odontological Society, June, 1894.

The inability to masticate food in order to prepare it properly for gastric digestion, the constant nervous irritation caused by the exposure of one pulp chamber after another, the accumulation of putrid and decomposing material in cavities already the home of innumerable bacteria with the vitiated secretions, are in themselves sufficient to produce in the growing child a lowered vitality which renders him a ready prey to other disorders of the body. Add to all this a weakened bodily tissue in which heredity has played an important part, injudicious feeding in which ignorance of what is best and how to prepare it is always evident, with lack of cleanliness and much which tends to make life worth living even among the poorest, and you have some explanation of how dental disease may be related to other diseases. In the first few years of my attendance at the Evelina Hospital I was in the habit of trying the effect of constitutional methods alone where there were no immediate signs of dental pain—that is, by prescribing some medicine (nothing satisfied the mothers of these patients better) and lecturing the mothers on food and the way to prepare it—but it was a slow and wearying process and it had to be abandoned. Many of my colleagues do the same thing but a glance inside the children's mouths is sufficient to make them send the patients on.

In some of these cases mentioned this treatment has been tried and abandoned. *Active dental treatment is absolutely essential* and by the satisfactory results obtained you have a proof of how readily the young respond to treatment which goes to the source of trouble. There is another point which I must not fail to notice, though it has been incidentally referred to—viz., the accumulation of the products of putrefaction within the mouth. This is not only occasioned by teeth in varying stages of disintegration with the decomposing food around them but by marginal inflammation and ulceration of mucous membrane and gum tissue encircling the teeth—stomatitis in various forms. They may vary and there may be different forms according to the bacteria found in the discharges or vary according to the degree of severity; that, however, does not concern me now: it is the fact of stomatitis being present, and as a consequence of lowered vitality it is typical. There is a wound in the mouth, a foul discharge, with an extra recruiting ground for bacteria. Some of these may find their way into the blood directly; most are passed on to the stomach. In one case they produce all the symptoms of acute toxæmic poisoning, or should the gastric juice of the stomach fail to destroy them there is a slow toxæmia by absorption through the alimentary canal. In 1895 I referred to this subject and published two cases on the clinical side. Here is a typical one[4]:—

> A girl, aged 11. Admitted as a case of tubercular meningitis. Emaciation extreme, marked anæmia, constant vomiting. Breath most offensive. The child seemed almost moribund. The mouth was cleansed with pot. permang. for three days, then seven carious teeth were removed. She was given full diet. In eight weeks her weight increased from *39* pounds to *64* pounds. Seven months later she weighed *81* pounds.

This systemic poisoning from bacteria within the oral cavity Dr. W. Hunter describes as oral sepsis and at Oxford he reported a series of remarkable cases which were published with a full discussion[5] and papers were read by members of this society on the same subject. It is not my intention to enter into details but simply in passing to note the facts that in adult life one is constantly receiving evidence of modified forms of systemic poisoning due to neglected teeth and to utter a word of thankfulness that a subject so long neglected by our medical *confrères* is at last receiving some attention. Apart from the special susceptibility which some men show to the inroads of bacteria or the special malignancy of some bacteria upon apparently healthy individuals, as when typhoid fever or tubercle destroys the life of the finest soldier or athlete, it is evident that a body whose vitality is lowered forms the most prolific ground for their development. With children this is so evident that you may see the effects of dental disease upon their bodies in a hospital the like of which is not to be found in private practice, unless that practice is among the poorest. I believe that defective dentition needs oftentimes the association with other diseases in order to show those defects in the clearest light. The following will serve as an illustration.

In THE LANCET of Oct. 29th, 1904, p. 1204, five cases of actinomycosis are recorded. The first three, entitled "A Clinical Study of Actinomycosis," are recorded by Dr. R. Knox. The patients were a girl, aged 18 years; a boy, aged 15 years, a brother of the girl; and another brother, aged 17 years. All these patients were suffering more or less in their general health. They were all sent to a farm in Perthshire where cattle had died from anthrax or some other disease. All had carious teeth with alveolar abscesses and glandular infection. In the first case throughout its course alveolar abscesses appeared in the mouth; pus from one of these was examined and contained the organism. Apparently the teeth were not treated by a dentist. This patient sank and died. In the second case the boy had some trouble with defective teeth with alveolar abscesses before his illness and these were treated by a dentist. This boy recovered. In the third case the boy was suffering from an abscess in the neck and he had adenoids. "His teeth were faulty; he had pyorrhœa alveolaris. A lower molar was extracted and had a saccular abscess at its roots." Pus from the tooth abscess and the one in the neck was examined; the mycelium with spores was found in pus from the tooth. The other faulty teeth were attended to, the adenoids were removed, and the patient made a good recovery.

The two cases reported from the Victoria Hospital were that of a girl, aged nine years, and that of a boy, aged ten years. The girl developed this disease in the skin of the chest and the boy in the skin of the abdomen. No site of infection was found but no mention whatever had been made of the condition of the children's mouths or their teeth. They were both improving in general health.

In conclusion, I have endeavoured to prove that the relationship between dental and other diseases is a very close and intimate one, as might have been expected. The defective dentition which we meet with in daily practice and among the poor as seen in hospital practice has the effect, broadly speaking, of lowering the nutrition of the body and by so doing opening wide channels by which other diseases are only too ready to find their way. We are face to face with the facts that dental disease is of all diseases the most prevalent among civilised communities; that we are as far from touching the cause of this defect as we ever were. We have in our own hands not only the means of alleviating much suffering but by systematic treatment improving the general health, especially of the young, who are in a sense the most important portion of the community.

A CASE OF

TETANUS SUCCESSFULLY TREATED WITH ANTITETANIC SERUM AND CURARE.

BY ETHELBERT COLLINS, L.R.C.P. LOND., M.R.C.S. ENG.,
CORONER FOR EAST HERTFORDSHIRE; MEDICAL OFFICER OF HEALTH OF THE URBAN DISTRICT OF SAWBRIDGEWORTH.

MY excuse for reporting this case is that one similar to mine was published in THE LANCET of Sept. 17th, 1904, p. 831, which recovered under the same method of treatment as that adopted by me. The case that I refer to received notice in an excellent editorial article on the Treatment of Tetanus which appeared in THE LANCET of Oct. 15th, 1904, which every medical man should read, and to which I beg to pay tribute. Therefore I trust that the following notes may not be without interest.

A healthy youth, aged 17 years, while at his work, brick-making, on Sept. 1st, 1904, trod on a rusty nail which perforated his boot and punctured the sole of his foot. His mother informed me that the wound "gathered" and that she poulticed it. The foot was well in a few days and the boy did not give up his work. On the 9th he felt some stiffness of his neck and jaw and could not masticate his food properly. I saw the patient for the first time on the morning of the 12th. He was then in bed sweating profusely and was unable to move. His teeth were firmly clenched, the muscles of his neck and back were in a state of tonic contraction, and the abdominal muscles were hard and rigid. The wound in the sole of the foot had quite healed and looked healthy, there being no tenderness In fact, all that could be seen was a black spot in the skin where the nail had entered The same evening, with the assistance of my partner, Dr F R B Hinde who in the meantime had seen the case with me and verified my diagnosis I freely excised the seat of puncture and swabbed out the wound with pure carbolic acid and packed and dressed it with sal alembroth gauze and wool We then injected ten cubic centimetres of antitetanic serum subcutaneously into the abdominal walls and ordered 20 grains each of chloral hydrate and potassium bromide every four hours

On Sept 13th, at 10 A M, the patient's condition was practically the same, he had no difficulty in swallowing and was taking liquid food well The pulse was 100 and the temperature was normal At 6 P M 30 cubic centimetres of serum were injected On the 14th, at 10 A M, he had had frequent attacks of tetanic convulsions during the night The teeth were firmly clenched, there was marked opisthotonos, the muscles of the thighs and the calf muscles were in a state of tonic contraction, the feet were extended, and the toes were flexed The abdominal walls were hard and the muscles were rigid There was slight risus sardonicus He was sweating very profusely Touching at once brought on tetanic spasms The pulse was 100 and the temperature was 99 4° F At 6 P M his condition was the same 30 cubic centimetres of serum were injected No serum was administered after this date On the 15th and 16th there was no improvement in his condition He still had frequent attacks of mild tetanic convulsions, but was taking liquid nourishment well On the 17th, at 10 A M he was about the same, he complained of great pain when "the cramp comes on" The pulse was 100 and the temperature was 98 8° One twelfth of a grain of curare was injected hypodermically into the forearm At 6 P M his condition was the same as in the morning One sixth of a grain of curare was given On the 18th, at 10 A M, he had passed a more comfortable night Muscular spasms were not so frequent or painful The pulse was 100 and the temperature was normal One sixth of a grain of curare was administered At 6 P M he had had very little pain One third of a grain of curare was injected

From Sept 19th to 21st the patient had been able to open his mouth slightly—about a quarter of an inch There had been no tetanic convulsions and he could move his head very slightly from side to side One third of a grain of curare had been administered each morning and evening On the 22nd and 23rd no curare was given On the 24th, at 10 A M, he had had a bad night There had been several severe convulsions His teeth were again clenched He was resting on the back of his head and heels There was slight rigidity of the muscles of the arms He asked to have his arm pricked again Half a grain of curare was injected At 6 P M another half a grain of curare was given On the 25t 10 A M one third of a grain of curare was administered 6 P M he was much better and was able to open his mc half an inch There were no convulsions One third grain of curare was given On the 26th at 10 A M he able to open his mouth and to move his head from side to side The muscles of the back the abdomen, the thighs and the legs were still in a state of tonic contraction There was no clonic spasm One third of a grain of curare was injected From Sept 27th to Oct 4th the muscular rigidity was gradually passing off and the patient was able to take solid food Half a grain of curare was given every evening After Oct 4th no curare was administered On the 5th, 6th, and 7th he was better and sat up in bed each day On the 8th and 9th he was out of bed and sitting in a chair On the 11th he was able to walk round the bedroom On the 13th he went down stairs and was feeling very well, his back was still a little stiff On the 15th he walked about the garden on the 16th he was able to walk well, and on the 18th he had recovered

From Sept 13th to 17th the patient was taking 20 grains each of chloral hydrate and potassium bromide every four hours On the 18th I decreased the dose to ten grains of each drug every four hours This dose he took until the 23rd, when I again increased the dose to 20 grains which he took every four hours till the 26th after which no more was taken The wound in the sole of the foot caused by the very free excision which I made was washed daily with carbolic lotion 1 in 40 and packed with sal alembroth gauze It healed without suppuration and never once caused the slightest pain

The pathology of tetanus suggests the rational treatment of the disease and before offering any remarks on the treatment I should like to point out the advisability of dropping the word "idiopathic" in connexion with tetanus as misleading There is no such thing as *idiopathic* tetanus Tetanus is an inoculable disease There must be a broken surface of skin or mucous membrane through which the tetanus bacillus is introduced or finds its way In the so called idiopathic cases the local injury—a mere prick or a scratch—has been so slight that the point of entry of the bacillus has been overlooked

In the treatment of tetanus prophylaxis plays an unimportant part Tetanus is so rare that it would be unjustifiable to employ such heroic treatment as would be necessary to destroy the bacillus even if we considered the possibility of its presence in every wound, or even in those wounds in which from their nature and causation, there is a greater possibility of its having been introduced Of course, every wound ought to be treated on strict antiseptic lines but this treatment is not sufficient to destroy the bacillus of tetanus which possesses great resisting power to the ordinary methods of destruction We know that the bacilli live multiply, and generate their specific poison in the wound itself and its immediate locality Therefore our duty is on the first manifestation of symptoms freely to remove the site of inoculation, when possible by the knife, otherwise by the actual cautery or scraping and in every case swabbing out the wound with pure carbolic acid

The question of amputation of a limb might arise on account of tetanus supervening upon some severe injury to the limb such as a compound fracture, a severe crushing, or a gunshot wound The question is a difficult one If the injury is very severe and symptoms of tetanus show themselves within five days after the accident the case is more than likely to be an acute one and the chances to be altogether against the patient's recovery In these circumstances I should advise amputation On the other hand, if symptoms do not appear until after the fifth day I would employ the best means at my disposal of destroying the bacilli and endeavour to save the limb

After removing the site of inoculation antitetanic serum should be injected under the skin of the abdomen in large doses (from 20 to 30 cubic centimetres) and repeated daily for a week or ten days Theoretically this should neutralise the poison already absorbed into the system, anyhow, it is the only means which we have of achieving that object and large doses cause no ill effects I cannot conceive that curare has a direct action on the specific poison but that it has some influence in diminishing the severity of the clonic tetanic spasms I feel sure it is said by paralysing the nerve endings It should be injected hypodermically morning and evening, commencing with one sixth of a grain and gradually increasing the dose, according to the severity of the spasms, Chloral hydrate and potassium bromide (20 or hours) appear to me to be ficial results in producing of the motor nerve cells Other details in the treatment of tetanus, such as absolute quiet in a darkened room, the administration of chloroform for relieving severe tetanic convulsions or for passing the feeding tube or catheter, and the choice of suitable aperients, need no comment

Sawbridgeworth

NOTES ON SOME INTERESTING SURGICAL CASES IN AFRICAN NATIVES

BY ALEXANDER R YOUNG, L R C P, L R C S EDIN,
L F P S GLASG,
MEDICAL OFFICER OF CHIOLE HOSPITAL, ANGONILAND BRITISH CENTRAL AFRICA

CASES recently published in THE LANCET by the Bishop of Zanzibar[1] and Mr P H Ward[2] of Lomagundi, Southern Rhodesia, show that African natives possess a great recuperative power which enables them to recover from some very serious obstetric accidents and surgical injuries The first of the three cases now described supplies a further instance of the same kind and moreover, in several respects resembles the one recorded by Mr Ward proved. The remaining seven cases in which bacteria were found in the uterus come, however, under a somewhat different category, inasmuch as it might be questioned whether the organisms found in the uterus were the actual cause of the illness. These seven cases comprise Cases 34 and 35, in which a "diphtheroid" bacillus was found in the uterus; Case 43, in which we obtained a pure culture of the staphylococcus pyogenes albus from the contents of the uterus; Cases 41 and 42, in which we found the staphylococcus pyogenes albus in the uterus in association with the bacillus coli communis; and Cases 14 and 44, in which we obtained from the contents of the uterus a pure culture of a diplococcus which did not stain by Gram's method and which grew freely on ordinary nutrient gelatin at a temperature of 20° C., and without liquefying the medium.

---

[1] THE LANCET May 7th (p 1278) and July 30th (p 301), 1904

[2] THE LANCET, Oct 15th (p 1060), 1904

Some account of the characteristics of the "diphtheroid" bacillus which we isolated from Cases 34 and 35 has already been published in Vol. LIV. of the Transactions of the Pathological Society, and we need only say now that morphologically the bacillus was indistinguishable from the bacillus diphtheriæ, but that it otherwise presented the following points of distinction: (1) it did not produce any acid in glucose peptone broth after six days' incubation at a temperature of 37° C.; and (2) it was non-pathogenic for the guinea-pig. We have found a similar "diphtheroid" bacillus in the cervical secretion of non-pregnant women, but it appears to us to be probable that in the two cases of puerperal fever in which we found it the organism was present in a pathogenic capacity. The bacillus which we have described is possibly the same species as that found by Halle in the vagina and believed by him to be the pseudo-diphtheria bacillus of Weeks. It is on record that the bacillus diphtheriæ has been found several times in the uterus or in the vaginal lochia but so far as we can ascertain the description of the bacillus found in these cases would apply to our "diphtheroid" bacillus equally as well as to the true bacillus diphtheriæ.

Cases 41, 42, and 43 can be dismissed in very few words; in the first two we found the staphylococcus pyogenes albus and the bacillus coli communis in the uterus; in the last we found the staphylococcus pyogenes albus in pure culture. In all these cases the symptoms were of what may be termed a "slight" character, but we are not prepared to suggest whether or not they were due solely to the bacteria which we found. It may be pointed out that, at any rate, the bacteriological examination of the vaginal lochia in these three cases showed the presence in each case of the same bacteria as we found in the uterus.

The last two cases of those in which we found bacteria in the uterus are Nos. 14 and 44 in Table I. In both these cases we found in the uterus in pure culture a diplococcus which presented certain distinctive characters. The organism was a largish coccus which had a marked tendency to a diplococcal arrangement; it grew freely on all the ordinary media, including nutrient gelatin, which was not liquefied; the organism did not stain by Gram's method. We found a precisely similar diplococcus in one of the cases in which we examined the cervical secretion of non-pregnant women and once in the vaginal lochia when the puerperium was normal and the uterus was sterile and we are unable to suggest anything as to its pathogenic importance in the two cases of puerperal fever in which we found it in the uterus. The cases were clinically very different; Case 14 was one of severe puerperal fever which died within eight days of the onset of unfavourable symptoms, but we did not make any examination of the vaginal lochia, nor was there any examination after death; whilst Case 44 was a very mild case of puerperal fever in which symptoms disappeared within three days and without any treatment, except intrauterine douching. We have been unable to identify this diplococcus with any of those which have been previously described as occurring in the genital passage of women. It is distinguished from the diplococcus which Bumm found in several cases of cystitis after labour by the fact that the growth on nutrient agar is of whitish colour and not yellowish as in the case of Bumm's diplococcus; and Bockhart's diplococcus which was found in cases of vaginitis, and which resembled this one in some respects, apparently was not decolourised when stained by Gram's method.

The frequency of occurrence of certain bacteria in puerperal infections.—Whilst our results correspond with those of the majority of workers at the pathology of puerperal infections with regard to what is perhaps the point of most practical importance—that is to say, the predominating importance of streptococci—there are certain other points as to which difference is noticeable. Our results have differed from those of some other writers with regard to the following points: (1) the relatively large number of cases in which we found the micrococcus pneumoniæ, certainly in four cases, and probably in two cases more; (2) the absence of the micrococcus gonorrhœæ in our series of puerperal infections; and (3) the absence of anaerobic bacteria, except for a single case in which a bacillus of this class was present apparently as a secondarily infecting organism. In illustration of these differences we may quote results obtained by Krönig, by Whitridge Williams, and by Vogel in their examination of the cavity of the uterus in cases of puerperal fever.

Krönig's results from the examination of 179 cases of puerperal endometritis were as follows: streptococci were found in 75 cases; staphylococci were found in four cases; the micrococcus gonorrhœæ was found in 50 cases. The remaining 50 cases were classified as "sapræmic"; in 43 of them no growth of bacteria could be obtained on ordinary media under aerobic conditions, but strictly anaerobic bacteria were found in 32, and therefore, presumably, in pure culture. It will be remembered that Krönig has also found the micrococcus gonorrhœæ and anaerobic bacteria in a certain proportion of the cases in which he has examined the lochia of normal puerperia.

Whitridge Williams gives the following results as obtained in the examination of the uterine lochia in 151 cases of puerperal fever: streptococci were found in pure culture in 31 cases; streptococci were found together with other bacteria (other than the micrococcus gonorrhœæ) in 13 cases; staphylococci were found in four cases; the micrococcus gonorrhœæ was found in eight cases; the bacillus coli communis was found in 11 cases; the bacillus diphtheriæ was found in one case; the bacillus typhosus was found in one case; unidentified aerobic bacteria were found in four cases; unidentified anaerobic bacteria were found in eight cases; bacteria were seen in coverslip preparations, but no growth was obtained, in 45 cases; absolutely sterile in 25 cases. With reference to two of the cases in Whitridge Williams's list, those in which the bacillus diphtheriæ and the bacillus typhosus are said to have occurred, it should be pointed out that in the first case full bacteriological proof of the identity of the organism present with the bacillus diphtheriæ was apparently not obtained, and with regard to the second case it is not clear whether the fever was due to a primary puerperal infection by the bacillus typhosus or whether the case was one of ordinary typhoid fever in the course of which labour supervened.

Vogel obtained the following results in a series of 24 febrile cases but did not use any special anaerobic methods of culture; streptococci were found in pure culture in two cases; streptococci were found with the micrococcus gonorrhœæ in two cases; streptococci with bacteria other than the micrococcus gonorrhœæ were found in three cases; the micrococcus gonorrhœæ was found in pure culture in two cases; the staphylococcus pyogenes aureus was found in one case; other aerobic bacteria were found in six cases; sterile, eight cases. Vogel remarks that the proportion of cases in which he found the micrococcus gonorrhœæ may, perhaps, be exceptional.

Whilst somewhat different results as to the precise causation of cases of puerperal infection may be expected in the examination of different series of cases, varying with the class of patient and the circumstances in which labour has occurred and in which treatment has been carried out, we confess that we are unable to offer any satisfactory explanation of the wide discrepancy between the results of the bacteriological examination in our series of 54 cases, and in the series of 179 which Krönig's statistics deal with. Even allowing for accidental failure of culture experiments it is difficult to understand how it was that in 54 cases we never found the micrococcus gonorrhœæ in the contents of the uterus and found an anaerobic organism only once, and as a secondary infection, when in his larger series Krönig found the micrococcus gonorrhœæ in nearly 28 per cent. of the cases, and anaerobic bacteria in pure culture in nearly 18 per cent. Whitridge Williams's results as regards anaerobic bacteria are probably not quite accurate as no cultures were obtained in a considerable number of cases in which bacteria were seen in stained specimens; but bacteria of this class were positively identified in about 5 per cent. of the series, whilst the micrococcus gonorrhœæ was found in exactly the same frequency. In Vogel's much smaller series the micrococcus gonorrhœæ was found in about 16·6 per cent. of the cases, whilst no deductions as to the relative frequency of anaerobic bacteria can be made in the absence of any attempt to isolate them.

Taking all the facts into consideration and allowing for the possibility that in one or two cases our methods may have failed to detect the micrococ[illegible]ia of the strictly anaerobic class [illegible] it is impossible to accept Kröni[illegible] the average frequency of occurr[illegible] puerperal infections. Kröuig's results also are remarkable for more than the mere frequency of finding of anaerobic bacteria; they are remarkable in that such bacteria were found in pure culture in as many as 32 out of 179 cases of puerperal endometritis examined. For, from what we know generally of infection by strictly anaerobic bacteria, there is reason to believe that in a very large majority of such cases the infection by the anaerobic organism is a secondary one; the conditions favourable to the growth of such bacteria are not found in a healthy wound such as the previously uncontaminated placental site presents. We realise that the peculiar conditions resulting from the retention in the uterus of what is practically dead tissue, retained placental fragments, or pieces of membrane would often permit a primary invasion by strictly anaerobic bacteria; but even so, we consider that Krönig's results with regard to the finding of anaerobic bacteria in cases of puerperal infection cannot be accepted as representing the average frequency of occurrence of this class of bacteria without further confirmation.

With regard to the frequency of occurrence of the micrococcus gonorrhœæ as a cause of puerperal fever there is a considerable difference between Whitridge Williams's 5 per cent. and Krönig's 28 per cent., the former not contrasting strongly with our own negative results in a smaller series. And here, again, we think that Krönig's results must be accepted with caution until confirmed by the work of others. We believe that undue importance has been attached to the micrococcus gonorrhœæ as a cause of puerperal fever by many writers; the bacteriological evidence of the frequency of gonorrhœal puerperal fever is open to question and the clinical evidence of its occurrence is often extremely doubtful.

We may next refer specially to those cases of puerperal fever in which the cavity of the uterus was found to be sterile of bacteria. Excluding cases of fever after miscarriage there were 48 cases of fever after labour at full term and in 33 of these we found bacteria in the cavity of the uterus. In 27 of these 33 cases the bacteria isolated were of definite pathogenic species and their presence in the uterus was sufficient to account for the symptoms of the respective cases; in the other six cases we found various bacteria of uncertain pathogenic action, but such that their presence afforded a reasonable explanation of the fever and no other more satisfactory explanation could be found. With regard to the remaining 15 cases in which no bacteria were found in the cavity of the uterus the following facts have to be noted:—

Severe cases (Series B).—Case 36: first pregnancy; laceration of the perineum; streptococci present in the vaginal lochia. Case 37: first pregnancy; laceration of the cervix and the perineum; streptococci present in the vaginal lochia. Case 38: first pregnancy; laceration of the cervix and the perineum. Case 39: second pregnancy; laceration of the cervix. Case 40: sixth pregnancy; no obvious laceration.

Slight cases (Series C).—Case 45: Second pregnancy; no obvious laceration. Case 46: first pregnancy; laceration of the cervix and the perineum. Case 47: first pregnancy; very extensive laceration of the perineum. Case 48: first pregnancy; laceration of the cervix and the perineum. Case 49: first pregnancy; laceration of the cervix and the perineum. Case 50: eighth pregnancy; no obvious laceration. Case 51: first pregnancy; laceration of the perineum. Case 52: first pregnancy; laceration of the perineum. Case 53: ninth pregnancy; laceration of the perineum. Case 54: first pregnancy; laceration of the perineum.

Amongst these 15 cases in which the contents of the uterus were sterile there were ten in which the patients were primiparæ, with, in every case, considerable laceration of the cervix or the perineum and in two of the cases streptococci were found in the vaginal lochia; in the remaining five cases the patients were multiparæ, and in two of these there was laceration of the cervix or perineum. Out of our 48 cases of fever after labour at full term, therefore, there were only three cases in which the occurrence of fever could not be explained with probability either by the presence of bacteria in the uterus or by the happening of laceration of the lower passage. These facts suggest that the probability of error arising from failure to detect the micrococcus gonorrhœæ or anaerobic bacteria in the course of our experiments may be regarded as comparatively small.

The influence of secondary infections on the course of puerperal fevers.—The relative importance of secondarily infecting bacteria is a question which must necessarily be considered in an investigation that deals with a class of disease in which there is every opportunity for secondary infection to occur. The results of our examinations with regard to this aspect of the pathology of puerperal fevers, and fevers occurring after miscarriage, may be stated as follows.

Series A.—Bacteria were found in the uterus in 14 severe cases which ended in death. A single species (streptococci twice) was found in four cases; streptococci and bacillus coli communis were found in five cases; streptococci, bacillus coli communis, and staphylococcus pyogenes albus were found in three cases; streptococci, bacillus coli communis, and an anaerobic bacillus were found in one case; micrococcus pneumoniæ, bacillus coli communis, and staphylococcus pyogenes albus were found in one case.

Series B.—Bacteria were found in the uterus in 21 severe cases which ended in recovery. A single species (streptococci seven times) was found in nine cases; streptococci and bacillus coli communis were found in one case; streptococci, bacillus coli communis, and bacillus pyocyaneus were found in one case; streptococci and staphylococcus pyogenes albus were found in four cases; streptococci, staphylococcus pyogenes albus, and an aerobic bacillus were found in one case; staphylococcus pyogenes aureus and bacillus coli communis were found in one case; micrococcus pneumoniæ and bacillus coli communis were found in one case; (?) micrococcus pneumoniæ and bacillus coli communis were found in one case; micrococcus pneumoniæ, bacillus coli communis, and staphylococcus pyogenes albus were found in one case; a "diphtheroid" bacillus and (?) another aerobic bacillus were found in one case.

Series C.—Bacteria were found in the uterus in four cases of slight fever which ended in recovery. A single species (staphylococcus pyogenes albus once) was found in two cases; staphylococcus pyogenes albus and bacillus coli communis were found in two cases.

Thus, out of 39 cases in which bacteria were found in the cavity of the uterus, in 26 more than a single species was present, and in a considerable majority of these cases of mixed infection either the bacillus coli communis or the staphylococcus pyogenes albus was present in association with the more virulent streptococci or micrococci pneumoniæ, which were, presumably, the primary infecting organisms.

Several writers on puerperal infection have held that the virulence of a primary streptococcic infection is greatly increased by a consecutive invasion of the uterus by the bacillus coli communis, and a reference to our results will suggest that there is a frequent association of these two species in severe cases of puerperal fever. But whether, as a rule, a subsequent invasion by the bacillus coli communis increases materially the severity of a streptococcic infection, under the given conditions, or whether it is the primary severity of the streptococcic infection which predisposes to a comparatively harmless secondary invasion of the cavity of the uterus by the bacillus coli communis, is not quite clear at present. In a considerable proportion of the cases in which we found a mixed infection by streptococci and either the bacillus coli communis or the staphylococcus pyogenes albus, the streptococci were present apparently in enormously preponderating numbers.

Taking a broad view, however, of the question in connexion with our particular series of cases it would appear that the finding of the bacillus coli communis in the uterine lochia in association [illegible] in relation [illegible] influence w[illegible] the case.

Sources of infection.—The source of infection in a case of puerperal fever may be found in the person of the patient herself or infection may be conveyed by those who attend her in her confinement. In the former case puerperal fever may arise from a spontaneous invasion of the uterus by bacteria present in the cervical canal or in the upper part of the vagina before the commencement of labour, or it may be caused by the conveyance of bacteria from the lower part of the passage to the cavity of the uterus by the manipulations of those who are attending on the patient. The conveyance of infection from outside sources by those who are responsible for the care of the patient during her confinement is a matter which has no special claim on our attention here; we may, however, mention that in our comparatively small series there were three cases of streptococcic infection which occurred within a short time of each other in the work of one practitioner, that a couple of cases of streptococcic and a couple of cases of pneumococcic infection occurred under similar conditions amongst the patients of two other practitioners. There has, however, been much difference of opinion as to the relative importance of auto-infection—that is to say, of infection from sources within the patient herself—in the causation of puerperal fever, and in this relation much work of investigation into the bacteriological condition of the cervical canal and upper part of the vagina in pregnant women has been carried out. And the general trend of teaching at the present time is that such source of infection may in a general sense be disregarded, and that the obstetrician has only to guard against infection from without.

Believing, as we do, that the most frequent cause of severe puerperal fever, and the most important factor in the causation of mortality from puerperal fevers, is one or other form of streptococcic infection, and there being also reason for believing that in a very large majority of cases of streptococcic infection the conveyance is from without, it is impossible to question the soundness of this teaching generally and for practical purposes. But if we consider all cases of puerperal fever, slight and severe, it is also impossible to doubt that a certain not altogether inconsiderable proportion do arise from auto-infection. So many investigations into the bacteriological constituents of the vaginal secretion of pregnant women have already been made that we did not think it necessary to re-investigate this subject and we think that an impartial review of all the work which has been carried out and published with regard to this matter will convince most obstetricians that the vagina and cervical canal of the pregnant woman may contain bacteria which are potential causes of puerperal fever. And, given the presence of such bacteria before labour, in the cervical canal especially, it is obvious that infection of the cavity of the uterus, or of lacerations of the cervix itself, must occur from time to time.

We have, however, made a bacteriological examination of the cervical secretion in 30 non-pregnant women with more or less catarrh of the lining of the canal in order to ascertain whether the bacteria which are to be found in the secretion in cases of slight disease are such as may be a cause of puerperal fever. As the result of our examination we found several bacteria which have already been referred to as being found in the uterus in cases of puerperal fever. Thus, we have found in both the cervical canal of non-pregnant women and in the puerperal uterus the staphylococcus pyogenes aureus, the staphylococcus pyogenes albus, the "diphtheroid" bacillus which we have described, a diplococcus which did not stain by Gram's method and was not the micrococcus gonorrhœæ, and another diplococcus which corresponded in every particular except pathogenicity for lower animals with the micrococcus pneumoniæ. We also found the micrococcus gonorrhœæ in the cervical secretion, although we have not been able to demonstrate[1] its presence in the uterus in any of our puerperal cases. Having regard to these results of the examination of 30 women, taken at random from amongst patients who complained of suffering from "whites," we think that it is obvious that opportunity for auto-infection must be of fairly frequent occurrence and it is probable that a very definite proportion of the cases of puerperal fever, of a mild type at any rate, arise in this way.

Conclusions.—We may now briefly refer to some points of practical interest which are suggested by the results of our investigation. In the first place it seems obvious that the old classification of cases of puerperal fever into sapræmic, septicæmic, and pyæmic has but little value; a comparison of clinical observations with bacteriological findings shows that it is practically impossible to distinguish between cases of septicæmia which are, for the time, of a mild type and cases of "sapræmia," using the latter term in what we apprehend to have been the sense in which it was formerly used in this connexion. And bacteriologically the distinction between a case of septicæmia and one of "sapræmia," or toxæmia as we would now term it, is often extremely indefinite. Whilst no really useful and at the same time concise scheme for the classification of a class of diseases presenting the variety of features which is presented in puerperal fevers is [illegible]ving scheme at any rate indicates the [illegible]sses concerned in the production of [illegible] infections:—

- I. Infection of lacerations of the perineal tissues or of the vaginal wall (sometimes with direct extension by continuity of surface to the cavity of the uterus).
  - 1. Localised infection + toxæmia.
  - 2. Localised infection + toxæmia + generalised infection.
- II. Primary infection of the contents of the uterus or of the placental site.
  - 1. Localised infection + toxæmia.
  - 2. Localised infection + toxæmia + generalised infection.

We have already said that perhaps the chief point which presents itself amongst the results of our investigation is the predominating importance of streptococcic infection in the causation of puerperal fevers. Thus, referring once again to the results of our bacteriological examinations, it will be seen that out of 14 cases of puerperal fever which ended in death, 10 were cases of streptococcic infection; that in 26 severe cases which ended in recovery there were 16 patients who had a streptococcic infection of the uterus and two who showed streptococci in [illegible]lst none of the 14 cases of [illegible] rising above 102° F.) had a streptococcic infection. And the next most important organism was micrococcus pneumoniæ, which accounted for three out of the four other deaths, whilst the cause of the remaining death remained uncertain. Infection by various strains of streptococci or by micrococcus pneumoniæ was present in 33 out of 40 cases of severe puerperal fever (Groups A and B), and these organisms may be held responsible for 13 out of the 14 deaths which occurred (Series A). And between streptococci generally and micrococcus pneumoniæ there are such close affinities with respect to pathogenic action that, apart from the question of specific antitoxic serum treatment, the same general treatment may be regarded as applicable to either.

We think, therefore, that we are justified in laying it down as a general rule that in the absence of a definite bacteriological diagnosis the safe course for the practitioner to adopt is to deal with every case of puerperal fever in which the temperature rises above 102° F. as if it were a case of streptococcic infection.

With regard to the question of the special antitoxic treatment of streptococcic infection there is very little that need be said now, the more especially so as one of us has recently dealt with the matter at some length.[2] We believe, however, that more than one species of streptococcus is met with in puerperal infections and that for serum treatment to be applied with any reasonable hope of success under present conditions a polyvalent or compound serum from a horse immunised against the various strains of streptococci which are met with in puerperal infections is necessary. And we believe that by the use of such a compound antistreptococcic serum, recently obtained from the horse and used in sufficiently large doses, a considerable reduction in the mortality caused by streptococcic puerperal fever could be effected.

The next point which we have to consider is the question of active curettage of the uterus in cases of puerperal infection. In the case of either a streptococcic or pneumococcic infection of the uterus, with or without secondary infection by other bacteria, this procedure would seem on the one hand to be incapable of doing any good, and on the other hand might be productive of most serious result by infecting the hitherto intact deeper tissues of the uterine wall. Nor, again, is it probable that in cases in which the uterus is invaded by bacteria which, unlike the streptococci and micrococcus pneumoniæ, have little tendency to infect the deeper layers of the uterine tissues, the operation is likely to effect any definite good by removing all infection, however thoroughly the curettage may be carried out. We consider, therefore, that the use of the curette should be absolutely discarded in the treatment of puerperal uterine infection.

---

[1] Full details of this series of cases will be found in the Transactions of the Obstetrical Society of London, 1905.

[2] The Treatment of Streptococcic Puerperal Fever by Antitoxic Serum, THE LANCET, Dec. 31st, 1904, p. 1823

The results of the treatment of some of the cases of streptococcic infection which have been dealt with in this paper have been such as to suggest that the best local treatment to adopt is that which is now commonly carried out in this country at the onset of puerperal fever—digital exploration of the uterus, the removal in this way of any retained fragments and subsequent douching of the cavity of the uterus with an antiseptic solution. A clinical fact of some importance is that, although invasion of the uterus by streptococci is marked by a sharp rise of temperature and other symptoms of some severity, the fever may be transient, subsiding within 48 hours without any special treatment. *This fact is one that may be usefully remembered* when tracing the conveyance of infection in puerperal cases.

The last matter which we have to refer to is the question of preventive measures which can be taken against the risk of auto-infection; the use more especially of vaginal douching with antiseptic solutions before the commencement of labour. We have the strongest doubts as to the effect of any such douching upon bacteria located in the cervical canal, such as those which we found in the cervical secretion of non-pregnant women, and regard the procedure as generally a useless one. But at the same time the objection which has been urged against it, that by means of it bacteria may be conveyed from the vulva to the upper part of the vagina, appears to be without good foundation.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A REMARKABLE CASE OF STRANGULATED HERNIA.

BY H. E. BARRETT, M.R.C.S. ENG., L.R.C.P. LOND.

THE following case will probably prove interesting to some readers of THE LANCET.

I was recently called to see a man, aged 77 years, whom I found dead on my arrival. I made a post-mortem examination which showed general peritonitis caused by a strangulated hernia, the gut being gangrenous, perforated, and united to the *bottom of the sac by recent adhesions*. The *hernia*, which was of the oblique inguinal variety, had not reached the scrotum. From the perforation there protruded what at first sight appeared to be a mass of fæces but on slitting up the intestine and removing this I found that it was a *portion of newspaper apparently* carefully folded up to about the size of a domino but slightly thicker, forming a hard angular mass; this was lying in the strangulated loop of intestine. Just above it there was another rather smaller piece also folded. They both had a *very slight fæcal envelope*. *At the inquest it came out that* the deceased had suffered from chronic constipation and I think it is not improbable that the paper might have been swallowed in the hope of obtaining an action of the bowels. The friends could throw no light on the matter. The paper when *unfolded* proved to be about a quarter of a sheet of the *Star* newspaper, the printing being none the worse for its journey through the stomach and small intestines. The hernia was an [illegible] there were no [illegible] except a slight [illegible] man died.

Holland Park-avenue, W.

NOTE ON A CASE OF OBSTRUCTION TO THE THIRD STAGE OF LABOUR BY A CERVICAL FIBROID.

BY W. BAIN, M.B., B.S. LOND.

THE following case, which occurred in the maternity department of the Middlesex Hospital presents some features that are interesting and uncommon.

The patient, a woman, aged 38 years, had had 12 children, the last one being two years old. When confined she was at full term and her pregnancy had proceeded normally. There was nothing to note about the first part of the labour beyond the fact that the size of the uterus and its irregularity suggested to the attendant the possibility of *twins*. The birth of the child took place naturally but was followed by fairly severe hæmorrhage which was, however, controlled by stimulation of the uterus and a hot douche. It was at this point that I was called in. The patient was very blanched and had a *pulse of* 140 *which was soft and feeble*. The placenta was still in the uterus. On palpating per abdomen the uterus was found to be fairly contracted and irregular in shape, a large prominence being felt on the left and another on the right.

On making a vaginal examination the passage of the finger through the internal os was prevented by a hard mass. On pressing in a direction almost directly forwards the obstacle was surmounted. The placenta was found to be imprisoned in the fundus of the uterus. With considerable difficulty and some renewal *of the hæmorrhage it was delivered*. The difficulty was rendered greater by the placenta being closely adherent to the uterine wall. After delivery the uterus contracted and the tumour was found to be a large fibroid situated in the posterior wall just above the internal os. The patient's condition *after* this was critical but after the infusion of two and a half pints of normal saline solution by way of the right median basilic vein she rapidly improved and made a good recovery.

The interest of the case lies in its demonstration of a well-known fact—the power which the uterus has of contracting and pulling a cervical fibroid above the presenting head. The subsequent sinking of the uterus into the pelvis caused the tumour to become an absolute bar to the passage of the placenta without help.

WESTMINSTER HOSPITAL.

A CASE OF ACUTE GLANDERS.

(Under the care of Mr. WALTER G. SPENCER.)

FOR the notes of the case we are indebted to Mr. M. J. Cromie, house surgeon.

A horse-keeper, aged 25 years, was admitted to the Westminster Hospital from an infected stable on Nov. 12th, 1904, at 8.30 P.M. A consultation between Dr. R. G. Hebb and Mr. Spencer at 11 P.M. lead to a surmise that the patient was suffering from acute glanders. On the following day Dr. Hebb found the bacillus mallei in cultivation. The patient died 33 hours after admission. Animal inoculations made at the *Lister* Institute proved the case to be one of acute glanders, the organisms being exceptionally virulent. A full consideration of the case exposes possibilities of infection and of such cases being overlooked.

The actual date of inoculation could not be verified. On *Oct. 31st* the patient fell while cleaning his stable and hurt his side to which a medical man applied a belladonna plaster. On Nov. 3rd he had pain and swelling of the left side of the face and went to a dentist who advised him to bathe his face in hot water and told him that an abscess was forming but *no* incision was made. He next saw two other medical men who told him that he had cellulitis and erysipelas. On Nov. 9th small hard lumps began to appear in the limbs in the neighbourhood of the joints, with pain in the joints, especially the knees. On this day, the 9th, the patient went *to* a hospital and on his out-patient paper was entered cellulitis of the face. An incision was advised, but as he could not be admitted and felt very ill he declined it. On the 10th the nodular swellings became red and inflamed and pustules appeared on the swollen face, the lips, and the buccal aspect of the lips and the cheek. The lips became black, nasal discharges commenced, and dyspnœa supervened. He was therefore taken to another hospital where he was given a paper saying that he was suffering from cellulitis and cephalitis (*sic*). Finally he was taken in an ambulance to the Westminster Hospital.

With regard to the stables in which the patient worked, his relatives stated that about a year previously a large number (they said 80) of horses in the stables had become glandered and had been condemned after the use of the mallein test. Further, that at the moment there were in the stables certain horses to look after which men were specially employed but that the patient was not one of these. After the relatives had carried back the diagnosis a further application of the mallein test showed a number of horses (it was stated 32) to be glandered.

On admission to hospital the patient was restless, slightly delirious, but could still speak clearly and partly answer questions. The temperature was 103·4° F., the pulse was 126, and the respirations were 38. The face and neck were swollen on account of an aggregation of pustules which had become confluent into a honeycomb-like mass. The pustules occupied the left cheek, the angle of the mouth, and the adjacent buccal mucous membrane and gums. Blackish crusts covered the surface which was not producing much discharge. There was no phagedænic or other marked odour. Pus escaped from the left nostril which was partly blocked by crusts. The rest of the face and the neck were swollen, of a dark-purplish colour, brawny near the pustules, with a fairly well-defined advancing edge. Both the eyelids were swollen as well as the temporal half of the conjunctiva of the left eye. Scattered over the neck, the trunk, and the limbs were seen (1) small erythematous areas with a papule in the centre; (2) small pustules with red areola containing thin pus; and (3) small ulcers. The size of the pustules varied from that of a pin's head to that of a pea. Especially along the lines of the lymphatics of the limbs were seen subcutaneous elevations which proved on touch to be hard nodules of the size of a hazel-nut, more or less, some of which were breaking down, and forming subcutaneous abscesses. None of them, however, came to the surface during life. The joints were painful but not felt to be distended with fluid. No glandular enlargements in the neck, the axillæ, or the groin were noted. The patient gradually became restless, sank, and died 33 hours after admission. Shortly before death he was breathing 68 to the minute, he had a pulse of 148, and a temperature of 99·6°.

Necropsy.—A post-mortem examination made by Dr. Hebb showed besides the superficial appearances above noted that the left cheek was swollen by inflammatory œdema and exudation, with abscesses in the skin and muscles. The muscles all over the body were the seat of numerous abscesses containing a thick sanious pus. The joints were normal. The mucosa of the nose and adjacent sinuses was much swollen and that covering the inferior turbinated bone resembled an aggregation of papillomata. But it is especially to be noted that there was no ulceration of the nasal mucous membrane. The lungs were engorged and the seat of numerous abscesses. Engorgement without abscesses was present in the spleen, suprarenals, and kidneys.

Bacterial observations by Dr. Hebb.—Films from the superficial pustules showed the bacillus mallei mixed with staphylococci, and cultures from the superficial abscesses were mixed, but pure cultures of bacillus mallei were obtained post mortem from the intramuscular abscesses. These cultures were sent to the Lister Institute.

Report from the Lister Institute by the Director.—The morphological and cultural characters of the organism correspond to the diagnosis of glanders. Inoculation of guinea-pigs resulted as follows: emulsion of agar culture 1·5 cubic centimetres intraperitoneally killed three guinea-pigs in 36 hours; 2 cubic centimetres of a similar emulsion given subcutaneously resulted in the animal's death in 40 hours. From these guinea-pigs the organism was re-obtained and gave the characteristic cultural reaction. The post-mortem appearances of the animals were not "characteristic" owing to the very rapid death of the animals but the main localisation of the organisms and inflammatory changes in the scrotum were well shown. The result shows that the organism is one of somewhat exceptionally high virulence.

Remarks by Mr. Spencer.—This case brings to light that in a large stable an epidemic of glanders recurs from incomplete disinfection and from keeping horses doubtful enough for special men to be told off to attend them and yet which were worked without being periodically submitted to the mallein test. Immediately on admission to the hospital Mr. Cromie telephoned me such good reasons for his opinion that I went at once to see the man and after doing so fetched Dr. Hebb. Neither of us had seen a case of acute glanders but the superficial pustules and the chains of nodules forming abscesses along the line of the lymphatics enabled us to confirm Mr. Cromie's surmises as to the nature of the case. On the next morning Dr. Hebb found the bacillus mallei in film preparations. Some months ago he discovered the bacillus in a case of chronic bone abscess under the care of Mr. C. Stonham, the diagnosis being proved as in the present case by animal inoculation. The patient had escaped a correct diagnosis earlier; except for his occupation there was nothing to connect him with the infection. There must have appeared on the cheek at an early stage discrete pustules, in which presumably might have been found the bacillus mallei. When I saw the patient the confluent pustules had begun to honeycomb the cheek. It was certainly not a case of phagedæna, there were no sloughs or odour. The surrounding swelling, although bluish, was not dark enough for anthrax and there was no central eschar. I had had just before in the same room a boy with what we were taught to call Paget's carbuncle, sent up from Westerham by Mr. H. H. P. Cotton, with the history that it had started with a wasp sting. The condition of the cheek was not very different and there were pains in the joints. It proved to be a pure streptococcal infection; the boy rallied at once after streptococcal antitoxin injections. I do not think the appearances of the glanders could have been mistaken for small-pox. Possibly such a case after death might have been registered as one of pyæmia and septic pneumonia. The virulence of the organisms is emphasised by the report of the animal inoculations. It is noteworthy that not only were the sores infectious but the lungs contained numerous abscesses and the patient's breath must have been infectious. I requested the two nurses on duty to wear rubber gloves and masks, otherwise they would have been exposed to considerable risk. The absence of ulceration in the nose of the patient, also of testicular changes in the inoculated animals, is accounted for by the virulence and rapid course of the disease.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Actinomycosis of the Gall-bladder.—Adenoma of the Gall-bladder.—Description of a New Method for performing the Operation of Jejunostomy.—A Series of 123 Cases of Choledochotomy for Calculi in the Common Duct.

A meeting of this society was held on April 11th, Sir R. Douglas Powell, Bart., the President, being in the chair.

Mr. A. W. Mayo Robson read an account of Actinomycosis of the Gall-bladder. He said that so far as could be ascertained by a search through medical literature bearing on the subject no case of actinomycosis of the gall-bladder had hitherto been recorded. The disease in this situation therefore was rare, though when it was borne in mind that no part of the body was exempt from the ravages of the fungus and that, next to the mouth and its neighbourhood, the abdomen was the most frequent site of disease it might have been reasonably expected that, like the appendix, the gall-bladder would occasionally have become invaded from the intestine. As in other successfully treated cases of actinomycosis, the treatment was at first surgical and subsequently medical. The history of the case was as follows. The patient, a man, aged 47 years, had for 18 months been losing weight and feeling ill; at first he had neither pain nor any signs by which he could localise his disease. After a time he began to have occasional attacks of pain in the region of the liver, but until three months before being seen by Mr. Mayo Robson the general symptoms of malaise only engaged his attention. For three months he said that he had never been a day free from bad attacks of colic and between these seizures there was a constant aching pain which he described as inflammatory and, in fact, the tenderness on the right of the abdomen at first led to a suspicion of appendicitis. There had been neither jaundice nor vomiting and his bowels were regular. On palpating the abdomen a decided swelling was at once found beneath the right costal margin, extending two inches below the level of the umbilicus. The tumour was continuous with the right lobe of the liver, was tender on pressure, and felt hard and irregular. The stomach was somewhat dilated but no succussion splash was obtained. There was no jaundice and no evidence of ascites could be obtained. A diagnosis of cholecystitis was made and an incision was made through the right rectus on to the swelling, which was found to be an enlarged gall-bladder adherent to the abdominal wall, containing pus and granulation-like material, with here and there suspicious yellow particles in it. The abdominal wall was not invaded but the omentum, the gall-bladder, and the right border of the liver were intensely bound together and invaded by the same granulation-like tissue. By means of a blunt-edged scoop the cavity was scraped out and afterwards irrigated, a moderate-sized drainage-tube being inserted, and the rest of the wound was closed. The progress of the patient was uneventful and recovery was complete. Three years later he was still in good health.

Mr. MAYO ROBSON then narrated a case of Adenoma of the Gall-bladder. He said that condition had been described as a pathological curiosity. The only other cases of which he had been able to find a description were one under the care of Dr. L. R. Sutherland, the specimen being in the museum of the Western Infirmary, Glasgow; one under the care of Wiedmann, referred to by Terrier and Auvray; and one described by Mr. Stanmore Bishop in THE LANCET of July 13th, 1901, p. 72. The interesting point in the present case was that the tumour produced symptoms exactly resembling those of gall-stones, characterised by spasmodic pains in the region of the gall-bladder, transient icterus, and deter[illegible] either have been due to the [illegible] acting as a foreign body, [illegible] by the neoplasm. The case was as follows. The patient, a woman, aged 53 years, had been subject to attacks of pain beneath the right costal margin for some months, the seizures recurring frequently and being associated with slight jaundice. A physical examination showed a slight enlargement of the right lobe of the liver, but the gall-bladder itself could not be definitely made out. There was slight tenderness in the usual position an inch above, and to the right of, the umbilicus in a line between the umbilicus and the ninth costal cartilage. As the patient had been under medical treatment for gall-stones for some time without obtaining any relief an operation was advised. On opening the abdomen a thickened gall-bladder was found under cover of an elongated right lobe of the liver but no gall-stones could be felt either [illegible] in the ducts. On [illegible] was made through [illegible] wall of the gall-bladder. It then became evident that the fundus of the gall-bladder was occupied by an adenomatous tumour. The loculi contained some particles of cholesterin. The cystic duct seemed to be narrowed and the remainder of the gall-bladder was small and thickened. Cholecystectomy was therefore performed in the following manner. The cystic duct was grasped within half an inch of the common duct by means of a pair of pressure forceps. The peritoneum of the duct was incised one-third of an inch above this and after stripping the peritoneum off the duct the duct was divided and ligatured close to the forceps. The [illegible] gall-bladder to the liver was [illegible] inch from its attachment to th[illegible] was then separated from the liver by the finger, working from below upwards, leaving about one-third of an inch of its peritoneal covering connected to the margins of the gall-bladder fissure of the liver. The peritoneum covering the cut end of the cystic duct was then brought together by a ligature, so as to bury the ligatured duct. After this the peritoneal margins of the gall-bladder fissure were stitched together from side to side so as completely to obliterate the groove in the liver where the gall-bladder had been attached. As no soiling of the peritoneum had occurred and all oozing had ceased it was not thought necessary to adopt any drainage and the wound was closed in the usual way. The after-history gave nothing special to record. The wound healed by first intention, the patient lost all her pain, and she went home at the end of the third week.

Mr. MAYO ROBSON then gave a description of a new method for performing the operation of Jejunostomy and concluded by reading a paper on a Series of 123 Cases of Choledochotomy for Calculi in the Common Duct. He said that on March 25th, 1902, he had read a paper before the society on the Surgical Treatment of Obstruction of the Common Bile-duct by Concretions, with especial reference to the advantages of an operation for the more complete exposure and treatment of the deeper parts of the biliary passages. The operation was fully described in the Transactions of the society for 1902. When this operation was first employed the mortality of choledochotomy including every case, whether complicated or simple, was 16·2 per cent. (21·4 per cent. in the first series and 9·3 per cent. in the second series, or together 16·2 per cent.), but since adopting the operation for complete exposure of the bile passages a continuous series of 76 choledochotomies had been performed for [illegible] of the common duct had been made the patients would have been unrelieved. On five occasions he had removed gall-stones from the common duct, although the patient would not confess to having had any pain, the operation being undertaken for deep jaundice associated with frequent rigors and high temperature. It had to be borne in mind that common duct cholelithiasis was, without operation, usually a fatal disease and that nearly every recovery was a life saved. —The PRESIDENT commented on the occurrence of gall-stones in the common duct without causing jaundice and asked Mr. Mayo Robson whether such was of frequent occurrence. He also asked what area of the surface of the liver it was necessary to use in forming the anastomosis between the abdominal wall and the liver for the relief of ascites. He further asked whether the capsule of the liver was removed in such operations.—Mr. J. WARRINGTON HAWARD said that he had not infrequently observed a gall-stone in the common bile-duct without jaundice. In a case of ascites due to cirrhosis of the liver on which he had operated he had formed an anastomosis between the two surfaces of about the size of the palm of the hand.—Mr. C. R. B. KEETLEY mentioned the case of a man with hydatid of the liver in which on opening the abdomen an abscess was found behind the gall-bladder containing pus and which after being opened discharged bile. He sought to explain the condition by the ulceration of a stone from the common duct into the abscess cavity.—Mr. MAYO ROBSON, in reply, said that he had seen numerous cases of stone in the common duct without jaundice and he thought the explanation lay in the fact that the stone did not completely close the dilated duct. He thought that the most unusual feature in these cases was the absence of pain, and he also thought that from two to three inches of the surface of the liver should be used in forming an anastomosis. He had never removed the capsule of the liver but he had done so with regard to the kidney.

MEDICAL SOCIETY OF LONDON.

Exhibition of Cases.

A MEETING of this society was held on April 10th, Mr. JOHN LANGTON, the President, being in the chair.

Dr. T. D. SAVILL exhibited a case of Paralysis of the Left External Pterygoid Muscle with Tremor of the Lower Jaw in a man aged 51 years. When he opened his mouth the lower jaw moved downwards and to the left. Possibly the internal pterygoid was also involved. There was also a constant rhythmical tremor of the jaw unless it was widely open or tightly shut, and to keep the jaw still the patient habitually kept a piece of wood between his teeth. The jaw jerk was increased considerably. There was no anæsthesia, loss of taste, or other symptom referable to the fifth nerve. The cause of the paralysis and tremor was obscure, but they had supervened about five years ago, about a year after a large number of bad teeth had been removed, the alveolus of the lower jaw on the left side being now notably wasted.—Mr. F. C. WALLIS had met with a similar case in a man who suffered from trigeminal neuralgia. On careful examination a few drops of pus were found to issue from a small hole in the jaw, from which one or two stumps were extracted, and the man got well.—The PRESIDENT remarked on the fact that the nerve to the external pterygoid was not near the teeth in the lower jaw and this suggested that the lesion of the nerve might be of reflex origin.

Society for the Study of Inebriety.—The quarterly meeting of this society was held on April 11th in the rooms of the Medical Society of London, Dr. Harry Campbell, the President, being in the chair.—Dr. Stanley B. Atkinson, barrister-at-law, opened a discussion on the Medico-legal Relations of Intemperance. He said that forensic medicine was the science and art of medical evidence. Most cases involving intemperance which came before the law courts were unreported, for they turned on some question of fact which, once having been adjudged by the jury, was not likely to form a precedent. There were, however, many points of law which a judge had to consider when dealing with persons "under the influence of drink." How far was that condition an excuse? How far was it an aggravation of the alleged offence? What was a habitual drunkard? How far did the lunacy laws operate upon inebriates? Forensically, there were three classes of intemperate citizens: 1. The police-court inebriate, who was usually set at liberty after a fine had been paid; occasionally he might be dealt with as a habitual drunkard. 2. The man who wished to be relieved by the court from the legal consequences of some untoward conduct during a fit of drunkenness which led to a criminally or civilly obnoxious result. The law presumed that a man was sober and he who affirmed the contrary must prove his allegation. 3. Whenever excessive drinking had been medically certified to be the cause of death the coroner should be informed of the fact of poisoning. It was very difficult to define what actually constituted drunkenness. A full clinical test should be applied to each case. The contemporary physical and mental health and the quality of the beverage would cause variations—a fact which helped to explain the different manifestations in men and in women. To three classes of the community the definition and the tests of drunkeness were especially important—namely, (1) the publicans, who must not allow a drunken person to be on their licensed premises; (2) the police, who were adepts in shifting responsibility by "sending for the doctor;" and (3) the medical man, who, at times, after considerable delay, became the final referee. It was judicious on the part of a medical man to give the patient the benefit of any doubt and tentatively to treat him as if suffering from a serious disorder unless and until its fleeting nature was proved. The past history, recent or remote, must not deceive him, either in dealing with the pre-comatose irritative stage or with the "dead drunk." There was no golden rule for testing drunkenness; abnormality in mental and in statical conditions was the most easily tested. It would appear from the wording of the Habitual Drunkards Acts that they referred only to the victims of alcoholic intoxication. Further, the Lunacy Acts did not embrace the inebriate as such; a man suffering from delirium tremens was not within their scope. Lawyers have long regarded drunkards as legally responsible for their moral irresponsibility. A few exceptions, however, were tolerated. Actual contemporary drunkenness, if proved, might excuse the unconscionable effects of a contract, or reduce a will, for in such instances the respective *consensus* and *animus testandi* were obviously absent. In criminal law no excuse was allowed unless delirium tremens was proved to have affected the passionate offender; but here also a few exceptions were tolerated, as for instance where a man was unwittingly drugged.

Liverpool Medical Institution.—The last meeting of this society for the session was held on April 6th, Dr. James Barr, the President, being in the chair.—Dr. W. Blair Bell explained his method of Mounting Specimens of Appendices in Clear Formalin Gelatin.—Mr. D. Douglas-Crawford showed an Appendix containing a Large Concretion. Beyond pain referred along the iliac branch of the ilio-hypogastric nerve no other symptoms were present.—Mr. C. H. B. Shears and Mr. E. M. Stockdale showed an Endothelioma of the Retina from a boy, aged three years. The sections demonstrated its origin from the retina showing the neuro-epithelioma.—Mr. R. C. Dun exhibited an Enteric Intussusception which had become gangrenous and irreducible and had been removed from a boy, aged four years. He considered enteric intussusceptions rare.—Mr. W. Thelwall Thomas, however, regarded this form as the usual one in children.—Mr. Dun also showed a Congenital Stricture of the Œsophagus from a child, aged three years. 17 months before death a gastrostomy had been performed.—Mr. Rushton Parker considered that this was an instance of maldevelopment.—Mr. Thelwall Thomas and Dr. E. Cleaton Roberts showed sections of a Non-traumatic Cyst of the External Ear, demonstrating the origin in primary degeneration of the cartilage itself.—Dr. W. Alexander and Dr. R. E. Kelly showed Sections Stained in Various Ways of a Portion of the Pre-Rolandic Cortex from the brain of an epileptic; they exhibited a nævoid condition of the vessels surrounded by old pigment and great atrophy of the white matter and corresponding cortex.—Dr. John Hay showed stained specimens of the Blood from a case of supposed Trichinosis. There was a leucocytosis of 20,000 and 24 per cent. of the white cells were eosinophiles.—Dr. J. Hill Abram demonstrated a Myositis in a patient whose symptoms had been attributed to eating sausage and in which the diagnosis of trichinosis was probable.—Dr. W. B. Warrington and Dr. F. Griffith demonstrated the existence of Fibres in the First and Second Dorsal White Rami of the Cat, the cells of origin of which were in the spinal ganglia.—Dr. R. J. M. Buchanan showed a series of lantern slides illustrating the Changes in the Blood in Spleno-medullary and Lymphatic Leucocythæmia with especial reference to the effect which the x-ray treatment had on the white cells. He regarded the leucocytosis of leucocythæmia and inflammatory leucocytosis as being essentially of the same order.—Dr. John Hay dissented from this view.—Dr. H. Briggs showed a large and beautiful series of Drawings and Paintings illustrating the Histology of Endometritis, Adenoma, and Early Carcinoma Uteri and discussed the value of the microscope as an aid to diagnosis in these conditions. Dr. Briggs and other speakers considered that not too much reliance could be placed on the examination of curettings.

Æsculapian Society.—A meeting of this society was held on April 7th, Dr. Leslie Durno, Vice-President, being in the chair.—Dr. David Ross showed a man, aged 27 years, who 16 months ago was operated upon for appendicitis; three months ago he was delirious from acute pain over the left colon and then examination per rectum gave intense pain at one spot. He is unable to follow his employment. He now wakes with pain in the morning and vomits "from the pain." The treatment by agreement of opinion advised was a reopening of the abdomen.—Dr. Alexander Morison read a paper on Fainting and "Sudden Death" under Exertion and in Allied States. In it, he said, the pulse and heart under exertion have quickened and increased in force; unless the right heart kept pace with the need of the systemic circulation blood to the nerve centres was diminished or absent from which fainting or death resulted; fainting, if by help from without or automatically the blood balance were restored; death, if that lost balance remained. He illustrated the argument by relating a case of a man, aged 35 years, who after a short swimming match sank and was taken out of the bath dead. At the necropsy it was found that death was due to heart failure; the right heart was distended with blood, the left was empty and contracted. There was slight fatty degeneration of the muscle fibres. Perhaps the most important form of fainting after acute conditions involving exhaustion was that associated with unconsciousness following severe convulsions from any cause. In that the resulting state resembles the condition consequent upon severe physical exertion leading up to exhaustion. Dr. Morison compared the vascular condition of acute pneumonia with the above and expressed his belief that the cardio-vascular stress in pneumonia resulted from the pyrexia and not from the obstruction of the lung. A lesson is to be learned from the depleted left and repleted right heart, which is the need for venesection aided by strychnine and rhythmical traction of the tongue. He illustrated that point by quoting two cases which were markedly relieved by venesection though death followed in the one case on the next day and in the other in three months while at physical exercise. A discussion followed, to which Dr. Morison replied.—Dr. Durno showed a Heart from a man, aged 70 years, who had died suddenly. He had had recurrent gouty arthritis and dyspnœa on exertion. The left heart was empty. The aortic valves were competent but calcareous; the mouth of one coronary artery was narrowed by the chalky deposit, and the aortic arch was markedly atheromatous.

Pathological and Clinical Society of Glasgow.—A meeting of this society was held on April 10th, Dr. Henry Rutherfurd being in the chair.—Sir Hector C. Cameron showed a patient suffering from Actinomycosis. When first seen there was a large swelling of the right cheek, apparently unconnected with the jaws. An abscess formed from which a large quantity of pus was evacuated, in which the characteristic organisms were found. At a second operation, some time later, scraping brought to light a grass seed (the species of which could not be exactly determined) which doubtless was the bearer of the infection. How it had entered the cheek was not clear but at any rate it had come from within the mouth.—Mr. J. R. Riddell showed a series of patients illustrating the Effects of Treatment with the X Rays. This included two cases of round-celled sarcoma, six of rodent ulcer, one of epithelioma of the lip, four of lupus, and two of keloid. The results on the whole were very satisfactory.—A joint communication on the subject of Glanders in Man was introduced by Dr. R. M. Buchanan.—Dr. A. K. Chalmers spoke of the prevalence of the disease in various stables in the city and the public health and economic conditions related thereto.—Dr. J. W. Anderson read notes of three cases in man; Dr. J. Cockburn Syson read notes of one case in man; Dr. Buchanan demonstrated the pathology of the disease by microscopic and museum preparations from man and the horse; and Mr. J. R. McCall, M.R.C.V.S., spoke of the rapid increase in the number of cases, the value of the mallein test for purposes of diagnosis, and the necessity of obtaining further powers to prevent the spread of the disease, and gave reasons for believing that it was reponsible for more deaths among men than was generally supposed.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on April 6th, Mr. G. Morgan, the President, being in the chair.—Sir W. H. Broadbent read a paper entitled "Clinical Illustrations of Pseudo-Angina and Angina" which will be published in THE LANCET *in extenso*. He described the pain of angina usually coming on after exertion or exposure to cold, the determining antecedent being an increase in the blood pressure of the arterial system. He discussed the various theories of causation and remarked that the most constant post-mortem finding was an atheromatous and sclerosed condition of the coronary vessels. He then dealt with hysterical pseudo-angina and next pseudo-angina of gastric origin, characterised by attacks at night or at the same time each day, giving instances of the satisfactory results of treatment of the stomach condition. He next described true angina associated with aortitis, with aortic valve disease, with atheroma of the aorta and syphilitic disease, and with fatty heart. For treatment he advised a quiet life with simple diet, mercury and iodides to reduce the vascular tension and to promote the excretion of toxins, and amyl nitrite and nitroglycerin in attacks, with erythrol tetranitrate to ward them off.—Dr. Walter Broadbent showed the heart from a case of Acute Aortitis, the patient having died from angina less than a week after the first attack.—Dr. F. G. Bushnell showed microscopic sections of the Aorta and of the Heart Muscle from this case and also discussed the paper.—Dr. E. Mackey asked whether in attacks of angina inhalations of oxygen were of use, also whether potassium iodide really reduced vascular tension, and discussed several other points in the paper.—The President, Dr. E. Hobhouse, Dr. F. J. Paley, and Mr. V. T. Greenyer also joined in the discussion.—Sir William Broadbent having replied, Dr. W. A. Hollis proposed a vote of thanks for the paper and Mr. C. J. Oldham having seconded it the vote was carried with acclamation.

ROCHDALE AND DISTRICT MEDICAL SOCIETY.—A meeting of this society was held on April 6th, when Dr. W. H. Carse read a paper on Vaccination. After a historical introduction he discussed the bacteriology of the subject, the method of obtaining lymph from the calf, and the effects of glycerine and of chloroform vapour on the lymph. He described his own method of vaccinating and showed the instrument which he used—an unsplit pen-nib. Three months was the best age for vaccination but postponement might be necessary owing to various circumstances. Finally the complications which might occur after vaccination were described.—Dr. W. J. Hodgson, Mr. G. W. Malim, Mr. H. H. I. Hitchon, Dr. A. Wallace, and Mr. W. Pooley (the President) discussed the paper.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held at the Royal Kent Dispensary, Greenwich-road, on April 7th, Mr. G. Chisholm Williams occupying the chair.—Dr. F. Harrison Low opened a discussion on Radio-Therapeutics, giving a short description of the appliances necessary and the methods of using Finsen's lamp, the x rays, radium, and high-frequency currents. He discussed the cases suitable for the different methods and referred to some points in the medical ethics in connexion with radio-therapeutics and electro-therapeutics.—The President showed some slides in the lantern of cases treated by these methods.—Dr. G. H. Graham showed four cases of Lupus treated by Radio-therapeutics; and Mr. Willmott H. Evans showed a case of Keloid treated successfully by the x rays.—The discussion was continued by many of the members present.

Reviews and Notices of Books.

A Text-book of Medical Practice for Practitioners and Students. Edited by WILLIAM BAIN, M.D. Durh., M.R.C.P. Lond. With illustrations. London: Longmans, Green, and Co. 1904. Pp. 1011. Price 25*s.* net.

MANY text-books of medicine have made their appearance within the last few years; American writers in particular have shown keen industry in the desire to occupy territory already somewhat overcrowded and yet it has been left to this country to produce a work of distinctly novel type. In all probability every clinical teacher continually refers to the elementary facts of anatomy, histology, and physiology in his demonstrations; it is convenient in addressing students to argue from the known to the unknown, to appeal to previous studies, and to encourage to further work by showing that medicine rests on certain foundations, even though to the beginner it may seem to be built upon the insecure basis of deductions drawn from the interpretation of physical signs. There is an inevitable contrast between the methods of the wards and those of the laboratories, and students who have passed the examinations in the earlier subjects are prone to turn with zest to the newer interests and to become absorbed in the keen acquisition of facts which seem to be more likely to influence the work of life. The teacher endeavours to counteract this tendency but it is to be feared that students rarely revert to the text-books which they have left behind them; life is too crowded, there seems so much to observe, so much to read, and the unity and the progressive character of medical training are apt to be ignored.

Considerations of this nature appear to have influenced the construction of this new text-book, since the separate sections are prefaced by articles on the salient facts of anatomy, histology, and physiology. These sections are contributed by Professor Arthur Robinson, late professor of anatomy at King's College, London, and by Dr. T. G. Brodie, professor superintendent of the Brown Institute, whose names afford sufficient guarantee of excellent work. The sections contributed by these authors are models of concentration and those dealing with anatomy are freely illustrated with clear diagrams from various sources. The medical sections are written by 14 contributors—Dr. Sidney Martin, Dr. C. O. Hawthorne, Dr. T. Wardrop Griffith, Dr. Alfred E. Russell, Dr. Percy Kidd, Dr. W. P. Herringham, Dr. Arthur Whitfield, Dr. J. S. Risien Russell, Dr. J. Dixon Mann, Dr. John Biernacki, Dr. C. Powell White, Dr. C. W. Daniels, Dr. J. Rose Bradford, and by the editor, Dr. William Bain. With so many different authors it is inevitable that the sections should be of unequal merit but in spite of the need of brevity the articles are generally both lucid and complete. In the section on Diseases of the Alimentary System, from the pen of Dr. Martin, we find much that is commendable and as an example of style and utility we would mention the admirable brevity with which he deals with the tongue as an index of disease; in less than and places. The author starts his diary at Tilbury Dock and in the first chapter we have an earnest that his eyes are open to impressions of all sorts and that his pen is ready to record them. The episode of the fond mother who has come to see her son off to India, weeping in seclusion behind a pile of rusty boiler plates on the quay while the son is drinking in the saloon, is exactly the kind of thing that might be expected to appeal to a hospital surgeon whose experiences both of that sort of mother and that sort of son are necessarily intimate. Gibraltar, Port Said (where the process of coaling is vividly brought before us), the Suez Canal, the Red Sea, Aden,—all receive description, and at length Bombay is reached. Sir Frederick Treves's first impression here is of the teeming life in India, the unwonted number of living beings, men and lower animals, who crowd the land. Next the fact is noted that India is a country of intense colour, as shown by its azure sky, the grey roads, the green cultivated fields, the many tinted costumes of the people, and the white domes and minarets of the mosques. This polychromatic scene is familiar to all of us, whether we have been in India or not, from the numerous illustrations of the country, but Sir Frederick Treves gives a dramatic point to the gay colouring that is prevalent by observing the apparent melancholy of the land and its people. The country is monotonous and often dreary as the traveller passes through its vast extent; the people talk little and laugh less as they tramp along in the dust; their religion is gloomy and their quiet fatalism might easily be mistaken for gloom. Then comes a chapter on the "Bazaars" of India, of which no more life-like picture has been drawn with the pen, so much so that on reading it the traveller is once again transported to those malodorous but fascinating quarters. We next come to the description of Agra, prefaced by a short account of the Moghul kings. The far-famed fort, the glorious beauties of the Taj, the tomb of Itmad-ud-Daulah, the marvellous city of Futtehpoor-Sikri, the mausoleum at Sikandra, the big mosque and the beautiful white palace of Delhi, Jeypore, Amber, Udaipur ("the most beautiful place in India"), and the dead city of Chitor all receive attention and ample justice from the author, who is clearly an enthusiastic sight-seer. Naturally, these scenes conjure up memories of the Mutiny, and the terror of that most awful passage in our national history finds full expression, both when discussing Delhi and when describing Cawnpore and Lucknow with their heartrending reminders of the terrible siege and the splendid relief. And so to Simla, now trembling in the agonies of an earthquake. Sir Frederick Treves visited this hill station in December, when the surrounding peaks are magnificent as viewed in their winter garments of snow, and renders cordial tribute to the lovely scene. Benares follows, and then, after a brief description of Calcutta, Burmah, the Golden Pagoda, the city of Mandalay, and the Irrawaddy are brought vividly before us. China was next visited and the result is a most realistic description of the city of Canton.

We have confined our running commentary mainly to Sir Frederick Treves's tour through India, but in Japan and the United States, on his homeward journey, he displays the same capacity for seeing things accurately and recording them sympathetically. "Trivial," to use the author's modest epithet, the book may be in the strict sense of the word, for the route gone over has been much traversed and the observations made follow aptly upon that route. But though Sir Frederick Treves has explored no hidden lands, has endured no arduous adventures, and has formulated no historical or ethnological hypotheses, though his tour was, as he styles it, commonplace, he has not written a "trivial" book according to the accepted and contemptuous usage of the word. On the contrary, he has given us an exceedingly well written and interesting volume.

Die Cystoskopie des Gynaekologen. (*The Cystoscopy of the Gynæcologist.*) By Dr. Walter Stoeckel. With nine coloured plates and many coloured illustrations in the text. Leipsic: Breitkopf und Haertel. 1904. Demy 8vo, pp. 333. Price 8 marks.

The importance of the diseases of the bladder to the gynæcologist can hardly be overestimated. The close anatomical relations of this organ to the rest of the pelvic organs, its frequent association with the affections of the uterus, and its liability to become involved in malignant growths originating in the genital tract render a knowledge of the various diseases affecting it most essential to all those concerned in the treatment of the diseases of women. A great deal has been done of recent years with the help of various forms of cystoscopes to enlarge our knowledge of the disorders of the bladder, and the ease with which it can be examined is in favour of the more extended use of the cystoscope.

This book by Dr. Stoeckel contains a very complete account of the subject of cystoscopy. The first part is devoted to a description of the instruments used and of the methods of their employment. A great deal of space is taken up with the details of the different kinds of cystoscopes and the various ways in which they can be employed, for example, catheterisation of the ureters, irrigation of the bladder, and the process of photography of the interior of the bladder. The author employs by preference the instrument devised by Nitze. The second half of the book deals with the different diseases of the bladder and its relationship to the various affections of the pelvic organs. Chapters are devoted to the condition of the organ in various pathological states of the kidneys and the ureters, in vesico-vaginal fistulæ and other injuries, in the diseases affecting the viscera in the neighbourhood, and, lastly, after the performance of different gynæcological operations.

The book should prove of great benefit to those operators who like to work with the instrument recommended by the author, but for our own part we think that possibly equally good results can be obtained by the use of the much simpler and more easily manipulated instrument of Kelly. The coloured plates are most interesting and are beautifully reproduced and the whole work bears evidence of the author's complete knowledge of his subject and is one which we can heartily recommend to gynæcologists and surgeons.

LIBRARY TABLE.

A Laboratory Guide in Elementary Bacteriology. By William Dodge Frost, Ph.D., Assistant Professor of Bacteriology, University of Wisconsin. Third revised edition. London: Macmillan and Co., Limited. 1903. Pp. 395. Price 7s. net.—The second edition of this book was reviewed at some length in The Lancet in 1902 so that detailed criticism of this new issue seems hardly necessary. The general plan of the book remains unaltered but minor changes have been made, such as the introduction of newer methods in place of the old and the rewriting of the directions for some of the experiments. The book furnishes instructions for a very complete course of practical bacteriology suitable for medical students and practitioners arranged in very logical sequence. It retains the distinctive characters of the former edition—namely, the arrangement of the work into short exercises so as to permit of easy adaptation to the requirements of various laboratories and the provision of blank forms for the study of micro-organisms which the student is supposed to fill up with the results of his own observations. This is a method which, if properly carried out, is of much educational value. Certain details criticised in the second edition have been altered but the dried-drop method for collecting blood for Widal's reaction is still the only one mentioned. The directions given in the section on Bacteriological Diagnosis are clear and good but whether they are sufficient unless supplemented by the instructions of a demonstrator is doubtful. Taken as a whole, however, the book fulfils its object very satisfactorily.

Higiene de los Trabajadores y Enfermadades de los Obreros. (*The Hygiene of Workers and the Diseases of Workmen.*) By Dr. AMBROSIO RODRIGUEZ. Gijón: La Industria. Pp. 447. Price 8 pesetas (about 5*s.*).—This book, according to its subtitle, is intended for the use of medical students, foremen, workmen, and others employed in industrial establishments as well as of sanitary officials. It is a popularly written account of the elements of public health and of the accidents which may occur in various industries such as machine shops, mines, electric works, and potteries, together with an account of the various diseases to which the different occupations may give rise. For instance, concerning laundrywomen, Dr. Rodriguez points out that they are liable to rheumatism, callosities produced by the use of the "dolly," catarrhal affections, amenorrhœa, œdema of the leg, varix, albuminuria, ulcers, prolapsus uteri, chilblains, and hang-nails or other ulcerations of the skin caused by the caustic soapy water. They may also contract infectious diseases, notably syphilis, from the dirty linen. The various occupations are dealt with in this fashion very thoroughly. Other chapters of the book are concerned with first aid, with sick and accident societies, and with the various toxic effects—e.g., lead or mercury poisoning—to which workers are liable. The book is well illustrated and should, we think, be found useful to those for whom it has been written.

The Gardening Year-book and Garden Oracle, 1905. By the Editor of the *Gardeners' Magazine.* London: *Gardeners' Magazine* Office. Pp. 287. Price 1*s.* net.—This is the forty-seventh year of publication of this useful work of reference on all questions which belong to the art and craft of gardening. It is the kind of guide which amateur gardeners require for constant reference, as it contains pithy reminders of what should be done in the garden and the greenhouse during each month of the year. There are a number of useful articles on such subjects as potato culture, strawberry and tomato growing, lawns and lawn games, rock gardening, climbing and rambling roses, hardy flowers, manures and their uses, and fungoid and insect pests. The article on potato culture gives valuable hints on raising and propagating new varieties, planting, manuring, and storing the crop, with a selected list of the best sorts to grow. The book is full of valuable information of an up-to-date character. An almanac and diary occupy the early pages.

Wisdom of the East, the Teachings of Zoroaster, and the Philosophy of the Parsi Religion, By S. A. KAPADIA, M.D. Brux., Barrister-at-law. London: John Murray. 1905. Pp. 104. Price 2*s.* net.—Out of the millions of believers in Zoroastrianism in the bygone ages there now remains but a handful of devout followers, known as the Parsis, but the author hopes that the strangers to the faith may find in it food for philosophic enlightenment and the Zoroastrians themselves a subject for deeper and wider researches in the untold wealth of sublime theology and philosophy, now locked up in the monumental tomes of the ancient Avesta writings. In an introduction, which is followed by some quotations from the "Sacred Books of the East," Dr. Kapadia gives a survey of the philosophy of the Parsi religion from the time when Zoroaster, the prophet of Bactria, preached nearly 3500 years ago to the present day. The religion is based on the worship and adoration of the "All-knowing Lord" and it speaks to its disciples (1) of the life on earth; (2) of the life hereafter; and (3) of the immortality of the soul and the resurrection of the body. Zoroastrian philosophy shudders at the contemplation of the mother earth being defiled by the burial therein of dead bodies and consequently means are devised of disposing of corpses on high mountain tops by birds of prey or by the process of nature. According to the book of the "Original Creation," at the time of the resurrection the soul will demand its original body out of the custody of the three known elements—the earth, the water, and the fire. All the dead will rise with consciousness of their good and evil deeds. At the Great Assembly, in the presence of the righteous, all will penitently deplore their misdeeds. Then there will be a separation of the righteous from the wicked for three nights and three days. At the end of this time the factor of evil goes to meet his doom of total extinction and God in his mercy permits all to pass through a bath of purification and to arise in sanctified purity. The descriptions of the ceremonies held to perpetuate the memory of the dead and of many others which are given in this volume add to its interest.

New Inventions.

A NEW COUCH FOR X RAY WORK.

Mr. Edward W. H. Shenton, L.R.C.P. Lond., M.R.C.S. Eng., radiographer to Guy's Hospital and to St. Peter's Hospital for Stone, has invented, and is using at Guy's Hospital, an x-ray couch specially designed to facilitate Roentgen ray work in hospitals and in private practice. The particular feature of the invention is the arrangement of the x ray tube which is fixed in a box and moves in longitudinal, lateral, and up-and-down directions under the table. These movements are controlled by turning two handles at the side of the table. The electric current is turned on and off by means of a footboard running along one side of the table, the ordinary incandescent lights of the room being turned on or off, as the case may be, simultaneously. To one side of the table is affixed a special holder for the screen, an ingenious arrangement allowing it to be adjusted to any height from the body of the patient convenient to the operator, while means are devised for turning the screen back to allow of a photographic plate being placed in position. The screen can afterwards be dropped into its original position if required. The top of the table can be converted into a carrying stretcher if necessary and the table itself, which is on castors, can be locked to the floor when required. The makers are the Sanitas Electrical Company, Soho-square, London, W. We have seen the table in use and the ease with which the operator worked would seem to show that it is a real economiser of the radiographer's labour, and what is equally important, it minimises the distress of the patient.

SOCIÉTÉ INTERNATIONALE DE LA TUBERCULOSE.—This society, the object of which is to study the most efficacious means of preventing and treating tuberculosis, held its annual general meeting in Paris on March 14th, under the presidency of M. Richelot, member of the French Academy of Medicine. After a discourse by Dr. Samuel Bernheim, in which he clearly set forth the actual state of the question, the society proceeded to elect its officers for the session 1905–06. The following gentlemen were appointed:—President: Professor Lancereaux, of the French Academy of Medicine, of Paris. Vice-Presidents: M. Huchard, M. Richelot, and M. S. Bernheim of Paris; Professor von Schrötter of Vienna; Sir Hermann Weber of London; and Professor de Lancaster of Lisbon. General secretaries: Dr. Georges Petit of Paris and Count Ivan Tolniewski of London. Treasurer: M. Papillon of Paris. Assistant treasurer: M. L. Garnier of Paris. Secretaries "de séance": M. Tartière, M. Bourdin, M. Roblot, and M. Chauveau of Paris. Archivist: M. Rualt of Paris. All applications for membership, &c., should be addressed to Dr. Georges Petit, 51, Rue du Rocher, Paris.

THE LANCET.

LONDON: SATURDAY, APRIL 15, 1905.

Proposed Confederation of the London Medical Societies.

ALL problems of evolution afford an interesting subject of study. Growth usually implies progress but may be attended by certain difficulties which have to be faced and which have to be overcome. With the progress of medicine there came a rapid growth of specialisation and it was natural that this should be accompanied by the formation of new societies for the comparison of experience and the discussion of improvements. These departures have followed natural laws along well-defined lines of cleavage and the general result has been satisfactory, since true progress can best be appreciated and abnormal tendencies checked by those who, by their training and experience, are in a position to separate the wheat from the chaff. This may be regarded as the justification for the formation of a large number of medical societies, and there is no necessity to take into account the local needs of the profession. Local societies should and will spring up wherever there are sufficient numbers for harmonious interchange of views on the difficulties of diagnosis or of treatment, or for the record of ethical matters. Frequently such meetings are of the nature of social gatherings which are of undoubted service in promoting good fellowship amongst those who are constantly meeting in their work. But such local societies, the number of which is large and might well be larger when the vast size of the district called London is considered, are outside the purview of the evolutionary development which is now to be considered.

Although division and subdivision must be regarded as inseparable from healthy growth, it is clear that there are inherent dangers in the process unless some link with a coordinating centre is retained. There is a natural and and very proper fear lest specialisation should lead to a lack of the sense of proportion or even to error through unduly focussing light upon a small portion of the field while the rest is left in darkness. Moreover, there is the question of finance which undoubtedly accompanies the evolution of new bodies and causes many to pass through periods of anxiety. Multiplication entails expense in the management, and the cost of belonging to numerous societies undoubtedly limits the aspirations of many of the younger generation. Concentration or federation would seem to supply a means of reducing this cost and thus of reducing the annual subscriptions while conferring desired privileges upon all. Although it would seem essential that the constitution of a coördinating centre should involve some principle of parental control due liberty of action might be given to all constituent sections. To facilitate the enjoyment of more numerous points of contact would tend to the advancement of medicine and to the diminution of any undesirable tendencies of specialism. The younger men would benefit from any scheme of concentration or federation which would give greater freedom of selection. In early days of practice, before the conditions of work have led to specialisation, many derive great advantage from roving from one society to another; and even later there are many occasions upon which all members of the profession are interested in the subject under discussion at one society. As it would seem reasonable to desire at that society the presence of all who might usefully contribute to debate the arguments for confederation of the London medical societies will be seen to have considerable force both scientifically and economically.

The meeting at the Royal College of Physicians of London on Monday last (see p. 1020 of our present issue) at which the proposed confederation of the London medical societies was considered, must have surprised even those who were the most sanguine supporters of the scheme. On a wet afternoon the attendance of about 200 members of the medical profession sufficiently indicated the general interest in the proposals, but in view of the history of previous efforts it could scarcely have been expected that unanimity would have prevailed. Sir WILLIAM S. CHURCH, President of the Royal College of Physicians of London, had been asked to convene a meeting and to preside at it, and he opened the proceedings with a brief historical sketch of previous efforts to fuse the principal societies. The failure of all of these might have caused much discouragement had not Sir WILLIAM CHURCH tactfully referred to the causes of failure in an early part of his address and suggested that federation did not involve fusion with the loss of identity. This line of argument was indeed foreshadowed in his letter, which we published on April 1st, 1905, p. 886, and in which he spoke of the attempts to "unite the various London societies representing medical science and practice more closely, so as to form a united Royal Society or Academy of Medicine, in which the existing societies would retain their individuality as sections of the united body." It is evident that, in his opinion, all previous efforts were wrecked on this question of fusion or absorption, and that the only chance of success was the formation of a new central body with a new name of a sufficiently wide character to permit federation without loss of dignity and without danger of invalidating title to property. While it was essential to obtain agreement on broad principles, it was impossible to enter into any detailed discussion of a scheme; in fact, the proceedings speedily proved the wisdom of narrowing the issue to a simple expression of opinion on the question of union. The use of the term the "principal societies" in the first proposition appeared likely to cause some discord. Sir WILLIAM CHURCH spoke of the "central societies" and explained that this term included all those meeting at 20, Hanover-square, or at 11, Chandos-street. This limitation excluded those societies which may be regarded as *local*, such as the Harveian and the Hunterian, though their claims for consideration cannot be ignored should they wish to join.

The meeting readily supported the first proposition, "That in the opinion of this meeting, convened by the President of the Royal College of Physicians and composed of Fellows and Members of the medical societies of London, it is highly desirable that an effort should be made to unite the principal societies into a new body, to be known as the Royal Society of Medicine." Some preference was expressed for a change of title, for the substitution of Academy for Society, and with a show of reason it was urged that constituent societies might more readily retain their name under the comprehensive term "Academy," but this was left as a detail for future consideration. A second proposition, which nominated a committee to make such inquiries as may be necessary and to submit a scheme of union to the various societies for their consideration, was adopted, and it was also agreed that a general meeting of the societies concerned should be convened in July next, if possible, to receive the report of the committee. Started with such enthusiastic unanimity it is to be hoped that no minor details may wreck the scheme. Its advantages are many and obvious, while the objections, which did not find voice at the meeting, are, it would seem, chiefly those of sentiment.

"Eugenics."

WE need make no apology to our readers for returning to the subject of the so-called science of "Eugenics," because if, as we understand Mr. FRANCIS GALTON to contend, it be indeed possible to elevate the general standard of the human race by judicious matrimonial selection, the enterprise is one not only eminently worthy of assistance from the members of a learned profession but also one in which it is practically certain that such assistance will be demanded from them by the public. Even now medical men are occasionally consulted as to the propriety or desirableness of some particular marriage; and we chance to have before us at this moment a letter written 50 years ago by an eminent physician now deceased which fairly expresses what we believe would still be a generally accepted point of view, although it would probably fail to satisfy Mr. GALTON'S requirements. In the case in question the writer, as physician to an insurance office, had advised an addition of from seven to ten years to the age of an applicant for insurance and he was written to, at the conjoint request of the applicant and of the father of a lady concerned, to ask "whether, on the ground of the applicant's health, he would object to his marriage with a lady in whose welfare he, the physician, was interested?" The reply was, "All other matters being favourable, I should not object to such a marriage. As the medical referee of an insurance office which is exceedingly particular as to the character of the lives which it accepts, I have thought it necessary to add from seven to ten years to Mr. A's age, with a view of thus covering certain risks which present themselves. These risks are not, to my mind, of a serious character, or the life would not be accepted by the office. They are merely matters of consideration in regard to the contingencies affecting masses of lives, but are scarcely sufficient to influence in any way the question of eligibility in a matrimonial point of view." The physician clearly entertained the opinion that he was not called upon to protect a lady against contingencies from which it was his duty to protect the insurance office; and this opinion would no doubt be based upon the extreme uncertainty as regards individuals of occurrences which are certain as regards a multitude. Here, indeed, is the crux of the difficulty. A million husbands, to each of whose ages a prudent insurance office would require an addition, would be practically certain to produce a generation somewhat inferior in health, strength, or efficiency to the offspring of a million selected lives. Whether one such husband would be certain, or even likely, equally to lower the standard of his single family is a question to which only a very few persons would venture to return a positive reply. It would, nevertheless, be the question on which a professor of eugenics would daily be asked to afford enlightenment and on which his decisions might exercise a very powerful effect upon the welfare and happiness of individuals or of families. Are there any data upon which such decisions could be securely founded? If there are we have yet to become acquainted with them; and, setting aside actual disease, we do not think it would be possible on the basis of any physical examination of a bride and bridegroom, or of any knowledge of their family histories, to arrive at even high probability with regard to the physical, moral, or intellectual endowments of their children.

We quoted Mr. FRANCIS GALTON on a former occasion as saying that the researches of the last 40 years had invalidated arguments which might formerly have been used against his contention, but no such researches have been brought to our knowledge. WEISMANN and others have suggested physical hypotheses by which the phenomena of atavism may possibly be explained, but these hypotheses cannot be said to have been established, and the phenomena, alike in their occurrence and in their uncertainty, have been familiar to the human race from the most remote antiquity. MALEBRANCHE knew nothing about chromosomes but he wrote in 1674: "C'est qu'il y a toutes les apparences possible que les hommes gardent encore aujourd'hui dans leur cerveau des traces et des impressions de leurs premiers parens." VOLTAIRE, contrasting the comparative certainty of the results of sexual unions in the lower animals with the uncertainty of the same results as observed in man, wrote: "C'est chez l'homme seul que le physique est dirigé et corrompu par le moral," and herein possibly—that is to say, in the influence of emotions and intellectual states—should be sough the explanation of many of the most perplexing incidents of heredity. Nothing has been established which throws any light upon the ordinary causes of the occasional predominance of one or of the other parent in determining the characters of the offspring, or upon the ordinary causes of unlikeness to either, which may often be due to an atavism not always admitting of being traced. Most medical men will agree, we think, that even when the wife has not been the predominant partner in earlie conceptions she is likely to become so if the nervous energies of the husband are engrossed by business anxietie or are weakened by illness at the periods of subsequen ones; and there have been well-authenticated cases in which such anxieties have witnessed the cropping up of previously unsuspected constitutional conditions. Soon after a great commercial failure, which led to widely diffused disaster, it was said that children subsequently born in some of the ruined families displayed marks of syphilitic inheritance from which their elder brothers and sisters had been free and that inquiry showed their fathers to have suffered from the primary disease before marriage and to have had medical authority for supposing themselves to have been cured. Not only business anxieties but the cares of State have often seemed to be unfavourable to the begetting of children inheriting the paternal qualities, and history is full of examples of great men whose sons have fallen lamentably below the paternal standard both in physique and in capacity.

It is certain, and, indeed, obvious beyond the reach of contradiction, that the tendency of the human race, when placed in favourable circumstances, is towards gradually progressive improvement alike in intellect and in physique but the course of this improvement is marked by eddies and backwaters of the most perplexing kind and is manifestly often modified by circumstances of which we have but limited knowledge and as to which we may easily be misled by ingenious guesses. Neither physiology nor genealogy in the least degree explains to us the genesis of the great man who springs up in the most unexpected places where no kind of ancestral preparation for his coming can be perceived. "Where there is nothing great to be done," said DUMOURIEZ, "there can be no great men," and it may be that mute inglorious MILTONS surround us on every side and that genius remains undeveloped in the absence of opportunity. It is at least certain that we cannot so arrange marriages as to secure offspring of commanding physical or intellectual power but it may be that we can so arrange them as to avoid the worst examples of decadence. It is obvious that we might raise the moral and the physical condition of the masses by education and by legislation and that the masses, if so raised, would in time supply the country with children prepared for still further advances in the same directions. The law, which has assumed the right of the nation to take possession of children for the purpose of sending them to school, should, in the opinion of many, clearly assume, as a corollary of that right, the kindred one of seeing that they are fed, and clothed, and washed, and withdrawn from circumstances likely to be destructive of their physical or moral welfare. If this could be done we should not require to select partners for the young men and maidens of the next generation but might permit them, as at present, to select for themselves, with the advantage of having better specimens to choose from. The middle classes might even go the length of looking coldly upon a combination of the small young woman with the small young man, but even then they should not be permitted to forget that brains are not always present in exact proportion to stature. We may, in short, treat the genesis of the coming race on such principles as to justify a hope in the gradual improvement of mediocrity, in whatever station of life it may be found, and the gradual improvement of mediocrity will be likely at once to push up those who are above and to drag up those who are below. The influence must, we think, be exerted rather upon the community than upon individuals with whom, in the present state of knowledge, it might often be hazardous to interfere. The marriage service of our church reminds us that the tie was instituted, not merely for the procreation of children, but also for the mutual help and comfort that the one ought to have of the other; and with this aspect of it we fear it would be dangerous for even a professor of eugenics to interfere. If we may reverse an old proverb, those who will have to lie upon a bed may at least claim to be given a free hand in making it.

◆

Epidemic Cerebro-Spinal Meningitis.

OF all the epidemic diseases attacking mankind epidemic cerebro-spinal meningitis, or cerebro-spinal fever as it is sometimes called, offers at the present time some of the most interesting problems for discussion. Although it is one of the most fatal of all acute diseases, as many as 77 per cent. of the cases proving fatal in some epidemics, yet owing to the peculiar local distribution of the epidemics it does not as a rule figure largely in the death returns. On the other hand, sporadic cases are by no means uncommon and it will probably be found when the bacteriology of cases of meningitis is more systematically investigated that the number of cases of this disease is much larger than is commonly supposed. At the present time the question of its epidemic spread is occupying the attention of both the lay and the medical press owing to the comparatively large number of cases occurring in certain parts of America and Germany. In New York during the month of February 149 deaths occurred from this disease and so serious is the view taken by the city board of the epidemic that an important commission has been appointed to investigate the disease and to endeavour to devise means to prevent its spread, as mentioned in our New York correspondent's letter in THE LANCET of April 8th. Again, in the neighbourhood of Kattowitz in Silesia over 450 cases have recently occurred with a mortality of 37 per cent. and considerable alarm exists at the prevalence of the disease. The term meningitis was introduced by an army surgeon named HERPIN in 1803 but the first recognition of meningitis as a specific fever was due to VIEUSSEUX of Geneva, who studied an epidemic which occurred there in the winter and spring of 1804–05. The first epidemic recorded in America was that occurring at Medfield, Massachusetts, in 1806 and described by DANIELSON and MANN. No doubt the disease had been prevalent before this time but it was probably confused with typhus fever and other eruptive febrile diseases, a confusion which has persisted until comparatively recent times (the late Dr. MURCHISON regarding the disease as a variety of typhus fever) and which is likely to be perpetuated by the name of "spotted fever" often popularly applied to the disease owing to the frequent occurrence in certain epidemics of herpetic, erythematous, and petechial rashes which, however, are not by any means constant or characteristic. Since 1806 epidemics have occurred in many different parts of the world, notably in America, in Ireland, and in Germany. A few minor outbreaks have been recorded in this country but the number of persons affected has, in nearly all cases, been very small.

As long ago as 1887 WEICHSELBAUM isolated an organism from certain cases occurring in Vienna to which he applied the name of diplococcus intracellularis owing to the fact that it is frequently found in the polymorphonuclear leucocytes. His observations attracted very little attention, especially in France and in this country, where the disease was regarded as due to the pneumococcus, or a modified form of that organism, a view which was apparently confirmed by the close relations existing between it and pneumonia which both present the same seasonal incidence, are associated with herpes, and with a similar leucocytosis and a fibrino-purulent exudate. Moreover, both diseases may occur in epidemics at the same time. In 1895 JAEGER, however, fully confirmed WEICHSELBAUM'S observations and the general result of modern bacteriological investigation of these cases has been to substantiate the claim that WEICHSELBAUM'S diplococcus intracellularis, or the meningococcus as it is sometimes called, is the causative agent of the disease. Two other points of great interest are that in the sporadic cases of cerebro-spinal meningitis occurring in London and other towns an organism presenting practically identical characters is obtained, while in the cases of posterior basic meningitis or "*cervical opisthotonos*" *occurring in infants* an organism has been isolated by Dr. G. F. STILL which has very closely similar characters. Our knowledge of the conditions leading to the epidemic spread of cerebro-spinal fever is of the scantiest. Epidemics most commonly occur during the winter and the spring and, it is said, especially after severe winters. Institutions such as barracks, asylums, prisons, and workhouses are peculiarly liable to be attacked and the disease is therefore apparently favoured by overcrowding. Its age incidence is peculiar, children and young adults being particularly liable, while above the age of 35 years it is very rare. In an epidemic occurring at Dantzic in 1865 93 per cent. of the fatal cases were under the age of 15 years. It is usually supposed that the disease is not directly infectious, or only very slightly so, but this is a matter which is not at present definitely settled and is one with regard to which the commission now appointed in New York may possibly afford us valuable information. Owing to the fact that the organism can frequently be obtained from the nasal discharges of patients suffering from the disease it has been assumed that the nose is the chief channel of infection; in fact, JAEGER thought that infection always occurred in this manner.

The morbid changes produced by the organism are those of a cerebro-spinal leptomeningitis with suppurative or fibrino-purulent exudate and increase in the amount of cerebro-spinal fluid with distension of the ventricles. The great liability to severe complications and sequelæ is also one of the serious features of the disease. Chronic hydrocephalus, blindness, deafness, arthritis, and periarthritis may be referred to as among the most frequent of these. The treatment has hitherto been mainly symptomatic, morphine or opium being the drug which has most generally been employed. Of late years the withdrawal of fluid by lumbar puncture has been tried as a palliative and curative measure. The suggestion to drain the fluid from the spinal theca was first made by Dr. W. ESSEX WYNTER [1] and this method was employed by him in a case of tuberculous meningitis in 1891. In the same year QUINCKE described the process of lumbar puncture as at present carried out, which is now extensively practised as a diagnostic measure, the cytological and bacteriological examination of the fluid removed affording very useful data. Repeated puncture has frequently been tried in cases of epidemic cerebro-spinal meningitis and different opinions have been expressed with regard to its utility. Professor W. OSLER in his Cavendish lecture delivered in 1899 described a case in which 17 punctures were made between the twenty-ninth and seventy-fifth days of the disease, but in spite of this the case eventually ended fatally. Dr. HERMANN LENHARTZ of Hamburg, who has observed 45 cases of the disease in the course of the past ten years, is convinced of the value of early and repeated lumbar puncture in the treatment of these cases. He records his results in an interesting paper in the *Munchener Medicinische Wochenschrift* of March 21st, 1905. The method which he adopted was to insert the tube between two spinous processes, the patient lying on the side with the thighs strongly flexed on the pelvis. The most favourable situation for puncture is usually the spot where a perpendicular line from the crest of the ilium cuts the line of the spine. As a rule about 30 *cubic centimetres were withdrawn and in no case more* than 50. It is advisable to measure the pressure of the fluid in millimetres in the spinal canal. This varied from 620 to 150 in one of his cases of which details are given. After withdrawal of the fluid it may be as low as 40 millimetres. Dr. LENHARTZ'S good results may possibly be attributed to the fact that he adopted lumbar puncture early in the course of the disease and repeated the process almost daily if signs of increased intracerebral pressure developed. Thus in one of his cases lumbar puncture was performed 15 times and a total quantity of fluid amounting to 400 cubic centimetres was removed. His observations are distinctly encouraging although he does not give statistics of the recoveries. In no case, however, were any unfavourable symptoms observed as a result of the puncture. The method is certainly a rational one, as it aims at keeping the pressure low in the cerebro-spinal canal by removing the excess of fluid and preventing it from accumulating. Dr. LENHARTZ'S paper is opportune in the time of its publication and we may hope that one result of the present epidemic may be an advance in the methods of treatment of this grave disease.

Annotations.

"Ne quid nimis."

THE BUDGET.

THE Chancellor of the Exchequer was received with cheering when he rose to make his Budget statement last Monday, for it was believed that he would be able to report establishment of equilibrium between expenditure and revenue. The estimated revenue of the country for the year 1905-06 turned out to be by nearly three millions superior to the estimated expenditure, though in one direction a heavy decline was shown. The revenue for 1904–05 from wine, spirits, and beer altogether failed to fulfil anticipations, for the amount realised was £1,516,000 below what had been expected. Mr. Austen Chamberlain considered that the figures showed us to be witnessing a change in the national character and that for the future Chancellors of the Exchequer must look less to Excise revenue than has been their habit in the past. This may be awkward for Chancellors of the Exchequer but it is excellent hearing for the public and for the medical profession, who for years have been preaching that improvements in the drinking habits of the country would mean a great gain in national morale and physique. We are only a little surprised that the spread of the doctrines of moderation in regard to alcohol, which has been so noticeable recently, has not sooner produced its mark upon the revenue. It is possible that the decrease in the wine duties may have been influenced to some extent by fraudulent competition, and our readers have good reason for knowing that this does occur; but the figures, as a whole, bear out Mr. Austen Chamberlain's interpretation that as a people we are showing a laudable tendency to spend less money upon alcoholic drink. "Twopence off tea" was his reward to a temperate nation for its eschewal of stronger liquor, the rest of the surplus going to the sinking fund and to reserve for contingencies. To medical men whose professional incomes often attain to the figure where the income-tax is most oppressive the fact that no abatement was granted on this toll must have come as a disappointment, but Mr. Austen Chamberlain's action in devoting a part of the surplus to the strengthening of national credit has been widely accepted as sound finance.

[1] THE LANCET, May 2nd, 1891, p. 931.

MANNERS IN THE LONDON STREETS.

The traffic of London has its daily complement of victims and the wonder is only why that complement is so modest. The element of thoughtlessness on the part of the foot passenger is responsible for most of the big catastrophes, wide-awakeness and freedom from pre-occupation being the two necessary factors for safe pedestrianism. The man who is absorbed in his ideas and fails to notice what is going on is the *bête noire* of the streets, obstructive to others and dangerous to himself. It is not so much the danger of the road traffic to which we desire to call attention as the carelessness of the public in perambulating the foot-paths. Many of them, in London at any rate, have no idea of avoiding collision with those whom they meet and no objection to blocking the way of those whom they precede. They throw the lighted ends of their cigarettes anywhere and may still spit despite the public agitation against the filthy habit. Sticks and umbrellas improperly carried cause many accidents. The proper way to carry these accessories is to hold them by the handle with the point down. The excited individual who raises his stick or umbrella in gesticulation runs a great chance of damaging someone. "A short time ago," writes a correspondent, who has addressed us feelingly on this subject, "I saw a gentleman severely injured in the eye by an over-eager passenger in an *omnibus* who raised his umbrella suddenly whilst gesticulating to the conductor and it is no uncommon thing to see ladies temporarily annexed by the handle of a passing umbrella tucked under the arm. It is the custom to advertise lessons in 'deportment' as one of the elements of the scholastic curriculum but the management of the stick and the umbrella appears to be neglected in this educational course and what might be made an ornamental addendum to the sartorial output becomes a dangerous nuisance, as witnessed in the swaggering switch in the hands of the new recruit or the careless twirl of the dandy's cane." We do not think "the twirl of the dandy's cane" is an expression founded upon observation, for the man of to-day does not happen to flourish his stick, but undoubtedly persons who carry their sticks and umbrellas under their arms horizontally pointed, or who thrust them upwards in the desire to hail a vehicle, are a public nuisance. Education in deportment, however, should not be limited to teaching "the nice adjustment of a clouded cane," and all parents should instruct their children to be thoughtful in the streets, thoughtful of what is going on around them and also of the comforts of the public.

THE VISIT OF FRENCH PHYSICIANS AND SURGEONS TO LONDON IN 1904.

The visit of the French medical men to London in October, 1904, is the subject of a most interesting article by Dr. Just Lucas-Championnière in the November number of the *Journal de Médecine et de Chirurgie Pratiques*, of which he is the editor. At the outset he remarks humorously that he was not without misgivings when it was found that the party numbered 150 members, but he acknowledges with satisfaction that the preliminary arrangements made by Dr. Sillonville and Dr. Triboulet were excellent and that the energy of the English executive committee enabled the visitors to see all that was possible of the London hospitals during the three days which were at their disposal. It was only to be expected that in hospitals, as in other institutions, and even in private houses, there should be some difference between French and English methods. Dr. Lucas-Championnière being a surgeon was naturally attracted by surgical details, such as the situation of the operation theatre at the top of the building and the careful administration of anæsthetics. He was also struck by the spaciousness of the wards and the ample distance between the beds. He writes enthusiastically of all that he saw and heard, with only two regrets—namely, that there was no time to inquire into the details of the public health service and that the state of Lord Lister's health prevented him from being in London at the time. The entertainments and other festivities were, he says, too numerous for individual mention but he devotes some paragraphs to the reception at the Royal College of Surgeons of England, the luncheon given by this journal, and the banquet at the Hotel Cecil. The article as a whole is very gratifying to English readers and admirably shows how community of idea in members of the same profession may encourage international amity.

YOHIMBIN.

A new drug is described in a recent number of the *New York Medical News* (Vol. LXXXV., No. 2) by Dr. E. B. Coburn and Dr. J. H. Claiborne. It is named yohimbin and is an alkaloid derived from the yohimbehe tree, a native of West Africa. It crystallises in silky white needles, is readily soluble in ethyl-, methyl-, and amyl-alcohol, and in ether and chloroform, but is only soluble in water to the amount of about 2 per cent. The hydrochlorate is usually employed but readily decomposes. It is said to be an aphrodisiac. ·25 cubic centimetres of a 1 per cent. solution may be subcutaneously injected without harm and a local anæsthesia is established which lasts for nearly two hours. It causes anæsthesia of the cornea and conjunctiva when dropped into the conjunctival sac. According to M. Magnani, who has recorded his observations in the *Annali di Oftalmologia* (Tome XXII.), though it produces smarting at first, it dulls the sensibility of the cornea in two minutes and destroys it completely after the lapse of ten minutes, the anæsthesia lasting half an hour. The effects on the pupil are uncertain and the drug has no effect upon the accommodation. Soon after the solution has been instilled the eye becomes hyperæmic, and hence M. Magnani suggests its employment in chronic affections of the eye which require stimulation. He prefers it to tropacocaine because its effects are more persistent, and to cocaine because it does not affect the epithelium or interfere with the nutrition of the cornea or produce mydriasis and hypotony. Moreover, it is not toxic. Dr. Claiborne made experiments on himself with solutions of various strength and also with solutions of yohimbin and adrenalin.

THE HUMANITARIAN LEAGUE.

WE have received from the honorary secretary of the sports' department of the Humanitarian League a circular signed with a number of names of more or less eminent men which has been addressed to the "Headmaster-elect of Eton." The signatories are made to say: "Without entering on the general question of the morality of field sports as practised by adults, we would express our conviction that it cannot be otherwise than demoralising for the *young* to be encouraged to seek amusement in the infliction of pain on animals, and that the permission granted to Eton boys to indulge in the sport of hare hunting, when drag hunting is readily available as a substitute, is greatly to be deplored." We do not know who is responsible for the drafting of this circular but we must reprobate in the strongest manner the assumption that Eton boys or any other persons who hunt are seeking amusement in the infliction of pain on animals. We do not deny that it hurts a hare or a fox or any other animal which is hunted by hounds to be caught and to be killed but we do deny that those who follow the hounds find their amusement in the infliction of pain. The recreation of one of the most eminent of the signatories is given in "Who's Who" as "sea-fishing," and we are quite certain that if anybody charged him with taking recreation by the infliction of pain on fishes he would be rightly much annoyed. We cannot think that those who have signed this circular have really gathered the meaning of the preface to which they have attached their signatures.

INFLUENZA, PNEUMONIA, AND HEART DISEASE AT CHICAGO.

THE department of health of the city of Chicago issues every week a leaflet which is extensively distributed to the press and to anyone whom it may benefit. This is done on the principle that sanitation is to a very large extent a question of education and that the best of laws will prove ineffective unless the people at large appreciate their importance and strive to apply them. By constantly calling attention to the various health problems as they arise the public is led to take an intelligent interest in such matters and then it is not so difficult to obtain popular sanction for necessary measures. For instance, at present, while the general death-rate is very low, there is a somewhat puzzling increase of mortality in regard to some diseases. Thus, during the decade 1880-89 the average annual death-rate from pneumonia was equal to 1·269 per 1000 of the population. During the last decade the annual average was 1·847 per 1000. This increase of 45·5 per cent. followed upon the epidemic prevalence of influenza which began at Chicago in December, 1889. But this is not all. During the earlier decade—that is to say, before the advent of influenza—the average annual deaths from heart disease amounted to 0·680 per 1000 and this increased 45·7 per cent. during the last decade and equalled 0·991 per 1000. The similar augmentation of fatality caused by these two diseases has given rise to the belief that influenza is the fundamental factor. During the present winter influenza has been more prevalent than at any time since 1891. Therefore special warnings have been issued urging that influenza is infectious and that the isolation of the patient and the ample ventilation of places and vehicles of public resort are the best protective measures. All excess, especially the abuse of alcohol, predisposes to this disease. The secretions from the nose, the mouth, and the throat of the patients teem with the influenza bacillus, and the department of health offers to disinfect the rooms, the bedding, and the clothes of all who have this disease. It is also urged that bacterial examination is of the first importance and the department of health places its laboratory and its experts gratuitously at the service of the public. Already the bacteriological laboratory claims to have found the influenza germ where there is an apparent simple coryza or uncomplicated influenza; then its presence has been noticed in conjunction with various other diseases, such as bronchitis, conjunctivitis, pulmonary tuberculosis, diarrhœal disease, diphtheria, empyema, endocarditis, meningitis, nephritis, middle-ear disease, mumps, pneumonia, scarlet fever, tonsillitis, and whooping-cough. The bacteriological laboratory also claims that cases which were mistaken for cerebro-spinal fever, lumbago, rheumatic fever, and typhoid fever revealed the presence of the influenza germ and therefore it is urged that more general use should be made of the facilities given for bacteriological investigation. In this latter respect the city of Chicago, in common with many other American cities, is to be congratulated on the possession of a public service of this description.

PROPOSED ADDITIONS TO THE POISONS SCHEDULE.

AT the recent monthly meeting of the council of the Pharmaceutical Society[1] a motion providing for the addition of certain poisonous substances to the Poisons Schedule was carried unanimously. The motion reads as follows:

[illegible]

According to the *Pharmaceutical Journal* the above recommendations can have no legal effect until the formal sanction of the Privy Council has been given, but the approval of that body has already been informally conveyed to the President of the Pharmaceutical Society. The proposed alterations, among others, were recommended two years ago by the Departmental Committee on Poisons and the council of the Pharmaceutical Society has taken action in the matter owing to the improbability of the subject of poisons receiving attention in the near future from the present Government. In taking this step the council has performed a public service. The poisonous substances named include cocaine and its salts, acetanilide, and sulphonal, substances which have during recent years become alarmingly popular with the general public. There is no doubt that the sale of cocaine has been to a very large extent restricted owing to the caution and discretion exercised by the large majority of pharmacists, and yet the "cocaine habit" is of so insidious a nature that within a quarter of a century of its introduction into this country it has claimed thousands of victims and has become a scourge second only to opium. It is to be regretted that writers of fiction should give prominence to habits so pernicious as the "cocaine habit" unless to condemn them. Thus, the vivid pen-pictures of Sherlock Holmes gained for that subtle detective at once a high position among the heroes of fiction. His methods came to be copied by would-be bloodhounds of crime, so much so that no self-respecting student of the subject would now attempt to tackle a problem, however trivial, without first shown. The revenue for 1904-05 from wine, spirits, and beer altogether failed to fulfil anticipations, for the amount realised was £1,516,000 below what had been expected. Mr. Austen Chamberlain considered that the figures showed us to be witnessing a change in the national character and that for the future Chancellors of the Exchequer must look less to Excise revenue than has been their habit in the past. This may be awkward for Chancellors of the Exchequer but it is excellent hearing for the public and for the medical profession, who for years have been preaching that improvements in the drinking habits of the country would mean a great gain in national morale and physique. We are only a ittle surprised that the spread of the doctrines of moderation in regard to alcohol, which has been so noticeable recently, has not sooner produced its mark upon the revenue. It is possible that the decrease in the wine duties may have been influenced to some extent by fraudulent competition, and our readers have good reason for knowing that this does occur ; but the figures, as a whole, bear out Mr. Austen Chamberlain's interpretation that as a people we are showing a laudable tendency to spend less money upon alcoholic drink. "Twopence off tea" was his reward to a temperate nation for its eschewal of stronger liquor, the rest of the surplus going to the sinking fund and to reserve for contingencies. To medical men whose professional incomes often attain to the figure where the income-tax is most oppressive the fact that no abatement was granted on this toll must have come as a disappointment, but Mr Austen Chamberlain's action in devoting a part of the surplus to the strengthening of national credit has been widely accepted as sound finance.

typhoid fever to the use of water from a properly constructed well, that is, from a well so protected that no water can enter without having percolated through eight or more feet of compact subsoil. He, therefore, points out that no one need hesitate about residing in the country merely because water has to be obtained from a shallow well, since by selecting a proper site and constructing the well with due care water can be obtained which is as safe as that supplied to any town. In a special section sanitary authorities are advised as to the steps which they should take to improve the water-supplies in their districts, and they are particularly recommended not to grant "certificates" to newly erected houses unless the water-supply is quite satisfactory and to furnish builders and others with instructions as to the proper construction of shallow wells, at the same time intimating that "certificates" will not be granted on shallow well supplies if such wells are not properly protected. This advice should be taken by rural authorities generally but it is a great advantage and a great benefit to the community when the county council is sufficiently enlightened to appoint a medical officer of health whose standing and experience qualify him to offer such advice and whose services are available over a large area. Such services are worth far more to a county than the most liberal remuneration that the officer receives, a fact which cannot be too strongly impressed upon those county councils which have not yet appointed such officers.

FIRST AID TO JOCKEYS.

Our attention is drawn by a correspondent to a defect in provision of medical attendance which certainly demands remedy. We refer to the want of precaution which obtains as regards the presence of a surgeon at the Liverpool race meetings, particularly in the case of the race for the Grand National. As many of our readers no doubt know, the course over which the steeplechase is run is one of the most severe that exists. The "fences" are high and the water jumps broad and, if further evidence were necessary to convince those who have never seen the Grand National course of the danger incurred in riding over it, the fact may be adduced that within the last three years out of 110 horses which have started for the race only some 40 odd have finished the course. It is obvious that where so many horses come to grief there must be considerable chance of injury to their jockeys. We believe it is the case that injuries more or less severe are common in all steeplechases and the Grand National is very far from being an exception to the rule. It would appear, then, to be a mere matter of ordinary foresight and humanity to insure the presence of a medical man, so that at least the removal of an injured jockey might be effected in a proper manner and so that any immediate remedy which is applicable might be applied. Dislocations, for instance, are common in riding accidents and may, of course, often be advantageously corrected at the earliest moment. We will not enlarge, however, on the obvious desirability of having a medical man on the spot at such race meetings. The fact is well recognised and at many, if not all, of the smaller steeplechase meetings a surgeon is regularly engaged by the authorities. The extraordinary thing is, as our correspondent points out, that at a meeting at which accidents are most to be expected, no such arrangement holds. If a jockey is hurt a notice is run up "Doctor wanted." If a medical man happens to be present he is sure to be willing to give his services but if not *tant pis* for the jockey. Liverpool abounds in able surgeons and there could be no difficulty in obtaining competent medical assistance for a salary well within the means of the authorities. The stands alone, we believe, earn many thousands of pounds. We trust that the attention of some member of the Jockey Club may be drawn to this matter, so that pressure may be brought to bear upon the proper persons to insure an alteration being effected in a state of things that is certainly at present far from creditable to those concerned.

ADVANCED PHARMACOLOGY AND THERAPEUTICS AT CAMBRIDGE.

In addition to the ordinary classes in general pathology and pharmacology it is intended to organise at the Pathological Laboratory of the University a series of short courses in which more advanced work will be dealt with. In the pharmacological section such subjects as bronchial asthma, vaso-constriction, the action and therapeutic value of adrenalin, the specific action of drugs, and the relationship of tolerance to immunity will be taken up by Dr. W. E. Dixon. In the pathological section Dr. G. H. F. Nuttall will deal with protozoa and the protozoal diseases, including the hosts and carriers of these protozoa, with sleeping sickness, kala azar, malaria, red-water, small-pox, and other fevers. In general pathology the subjects specially treated will be inflammation, immunity, antitoxins, bacteriolysins, hæmolysins and other "antibodies," food poisoning, and certain clinical methods arising out of recent investigations. We are glad to draw the attention of our readers to these courses as the demonstrations, being under the direction of Professor G. Sims Woodhead, professor of pathology in the University, are sure to be of the most practical and modern description.

PSYCHOSES DUE TO TRAUMA.

In reporting a case of mental disorder due to trauma in the *Allgemeine Zeitschrift fur Psychiatrie*, vol. lxi., part 3, Dr. J. Wende comments on the rarity of this condition and gives some interesting figures Thus Sachs and Freund could only with difficulty find a few instances amongst 20,000 cases of accident, whereas cases of traumatic neuroses occurred in abundance. Edel of Charlottenburg, dealing with material collected during two years, could only find cases of traumatic psychoses in some 2½ per cent. of all cases under treatment in that district where the large resident population of railway employés furnishes numerous cases of disorders due to accidents. Other statistics are those of Wagner (three cases of psychoses amongst 90 of head injury) and Stolper (12 cases amongst 981). It is pointed out that in these two latter instances the figures were collected from amongst workers in mines, in whom severe injuries of the head are unusually frequent. In the Franco-German war, amongst 8985 cases of injury of the head the Prussian "Sanitätsbericht" notes only 13 of mental disorder. Dr. Wende points out that in determining the mode of operation of an injury of the head it is necessary to distinguish between psychical and mechanical effects, for either may suffice to originate mental disorder. Where the effect is in the main psychical such disorder would not be expected to follow except in a predisposed individual. The mechanical effect, apart from cases of profound injury to the skull and the brain, consists in cerebral concussion, and this, according to the investigations of several writers whom Dr. Wende quotes, involves primarily the vaso-motor system and the walls of the blood-vessels; in the latter changes are found, such as hyaline degeneration, round-cell infiltration, aneurysmal dilatation, and endarteritis obliterans. As a result there are disturbances of nutrition with regressive changes in nerve cells and neurogliar cells. Cerebral concussion may be slight in degree and yet result in serious psychical disturbance. The traumatic psychoses present no uniformity of symptoms but comprise the most diverse states, from well-known mental disorders to those of undetermined character. There is, however, a prevailing

Admiralty, the War Office, and the Government of India because of their unsympathetic attitude towards their medical services it will be seen that the position of the officers of all three departments has been altered quite recently for the better in response to representations. The scientific ideal of our great bureaux is not high when medicine is in question, but it is stupid to represent the departments as wantonly and purposely unfair towards the medical man. Moreover, medical men have themselves much to answer for if the scientific side of medicine is occasionally belittled. Professor T. Clifford Allbutt, Regius professor of medicine in the University of Cambridge, recently called attention to the unscientific or even anti-scientific tone of the Army Medical Service as exercising a deterrent effect on medical candidates of a superior class. He spoke as being in possession of information showing that the senior medical officers in this service have a lack of appreciation of the scientific work of their juniors. "Science doesn't pay" expresses the views of these military-minded persons and this is the spirit which has damaged the three services so much and which, if it is not eradicated, will even now prevent their resuscitation.

The three services are taken in the following order: the Army Medical Service, the Indian Medical Service, and the Naval Medical Service, and in each case the old abuses are considered alike where they influence existing conditions, the present circumstances of the service, and the chances of improvement. In the case of the Indian Medical Service I have entered purposely with considerable detail into the matter of pay, as in this service the pay is distinctly bad. The scale on the civil side has not been altered for 30 years and unless alterations are made with promptitude the Government of India will be embarrassed seriously by the dearth of medical officers.

The Army Medical Service.

The Army Medical Service has been the best abused section of the medical profession. The public has slighted it, the War Office has neglected or mismanaged it, and its members have been in prolonged revolt against their conditions of employment. There is no use in going at any length into the disputes which for years raged in the medical journals under the title "The Reform of the Army Medical Service" and which have not yet been settled. But the various steps by which the department has been transformed during the last 14 years into what it now is must be outlined, for the past history affects the present condition and not in a very fortunate manner.

During the "eighties," and no further retrospection will be attempted, the service was full and fairly popular. The instruction at Netley, being intrusted to professors for whom no provision for superannuation or retirement had been made, tended to fall behind modern standards but the public did not lose much by this, for there was good competition for the commissions and a fairly able class of surgeon on probation was recruited. But a change came over the face of things in the next decade. That the conditions of employment were in some respects unfair became manifest. For example, it was not easy for an officer of the Army Medical Service to obtain satisfactory sick leave on full pay. He could have six months' sick leave on full pay, and this leave was renewable once. After that he went on half pay, unless the medical board from the first gave him a prolonged leave for his recovery—a privilege which was rarely, if ever, granted. Again, at a time which was marked by many-sided developments in medical knowledge, when in all the medical schools of the country the more brilliant and ambitious students were striving to benefit by the results of modern research, the Army Medical Service offered no inducements to scientific men. Thirdly, a difficulty experienced by the officers of the Army Medical Service in obtaining entrance to the "Service" clubs was not calculated to increase the demand for commissions. And so, for this reason or that, the applications fell off and competition became a pretence, for there were more vacancies than candidates. In 1891 came a new warrant which it was hoped would meet a case to the seriousness of which the War Office was awakening. This warrant provided that the officers of the Army Medical Service should have sick leave on full pay on the same conditions as those laid down for regimental officers and at the same time the designations of the departmental ranks of the Army Medical Service were altered by the granting of semi-military titles. The question of the use by medical men, who are officers in the army, of military titles is an unsettled one still in many minds. But the officers of the Army Medical Service were almost unanimous in their desire for this innovation, as being calculated to make their general position less insecure and anomalous; their brother officers of the Indian Medical Service had the same opinion, although not perhaps quite to the same extent; both were heartily backed in their views by the British Medical Association and the warrant granted their desire. All now should have been well, but, as a matter of fact, nothing happened. The Army Medical Service did not become more popular, the position of the officers did not improve, and the competition for commissions grew no severer. One class of young medical men were kept from joining the army by the difficulties that they heard would be put in the way of any desire to do original work. With another class the exclusion from "Service" clubs rankled, for many good men, forming the material from which members of a medico-military corps ought to be drawn, felt strongly that it would wound their self-respect to join a service where they were regarded by their brother officers as good enough to work with but not good enough to play with. Lord Wolseley, at that time Commander-in-Chief, was believed, with some show of reason, to view with dislike any acquiescence in the claims of the medical officers. Notwithstanding the multiplication of military-medical duties both at home or abroad, and notwithstanding the increase in the size of the army, the *personnel* of the Army Medical Service was less by 400—i.e., about 30 per cent.—than it had been after the Crimean war. The depletion of the establishment produced an unfair incidence of foreign service, great difficulty in obtaining reasonable private leave, and a constant change of station whereby hardship and expense were entailed upon officers of moderate means, especially if married.

In 1898 another new warrant was issued, under which the Army Medical Service took its place as a Royal corps side by side with the other scientific branches of the army—namely, the Royal Engineers and the Royal Artillery—a position which reformers had contended that it should properly and legitimately occupy. At the same time, and in analogy with the use of military titles by the Royal Engineers and Royal Artillery, such titles were assigned to medical officers up to and including the rank of colonel, so that there could no longer be any doubt about the exact army rank of the officers of the Army Medical Service. The warrant dealt simply with the constitution of the new Royal Army Medical Corps, but the regulation with regard to the use of purely military titles afterwards came into force in the Indian Medical Service. There seemed no reason why the Royal Army Medical Corps should not now become a deservedly popular service and attract a number of well-trained candidates from the universities and medical schools. THE LANCET, after the promulgation of this warrant, said, "Lord Lansdowne has done all he could to secure medical officers an assured rank and honourable position in the army worthy of the profession to which they belong, and his efforts in this respect deserve to be ungrudgingly and gratefully recognised." And many senior officers thought that the concessions of the War Office would prove successful in inducing a large and good class of men to compete for commissions in the Royal Army Medical Corps at the succeeding examinations. But again nothing happened.

The grievances of the service were so manifest that its advantages were lost sight of and yet these were, and are, very real. Medical employment in the British army offers, as a matter of fact, unrivalled opportunities and the records of certain officers show that it is not impossible to seize upon them. The sphere of activity is world-wide. Not even in our navy is there an equal chance of studying the diseases peculiar to particular lands and the imagination and professional interest must be dull indeed which cannot be quickened by a consideration of the varied field in which an officer of the Army Medical Service finds himself. The red tape, of the restricting bonds of which so much is talked, has not been able to stifle much original scientific work. The pay, though inadequate, is certain, and the social conditions, if not perfect, are at any rate more dignified than those of a large section of the civil medical profession. Some writers in the medical press, in the laudable desire of benefiting the officers of the Army Medical Service, appear to have damaged that service by the persistence with which the darker side was always presented. At any rate the medical profession and the teachers in the medical schools did not regard the warrant of 1898 as satisfactory and the Army Medical Service remained nearly as short of men as ever, which meant that the hardships dependent upon undermanning remained acute. And just when the service was in this condition, unpopular, dwindling, and overworked, the tremendous strain of the South African war was thrown upon it. What followed is too well known to need more than the barest recapitulation. Splendid work was done by officers of the Army Medical Service, but the department as a whole came in for severe criticism. Not one of the popular books dealing with the South African campaign failed to give a chapter or more concerning the Corps; while the serious works, as well as the letters of medical men at the front, dealt with its deeds in copious detail. Explanations of, and remedies for, the deficiencies which observant writers noticed in the medical work at the front were forthcoming in every direction, while deeply ignorant persons rushed to the rescue with impossible remedies for non-existent conditions. From every side, in fact, there was offered a rich choice of prescriptions for reviving the drooping condition of the Army Medical Service. Testimony to the devotion and skill of individual members of the Corps was as emphatic as any of the criticism lavished upon the faults of the system; but condemnation produces more effect and lingers in the memory more persistently than praise and the general idea gathered by the public was that, despite the skill and self-devotion of a few, the Army Medical Service had broken down badly. Of course, it did nothing of the kind. Its work as a department was more affected by the tremendous difficulties of transport than was the work of other departments of the army and all criticism that lost sight of this fact, however generously inspired, was unfair.

After the war came the Royal Commission to inquire into the management of the South African hospitals, the report of which, forming the first well-balanced and authoritative expression of opinion upon the medical conduct of the campaign, proved on the whole favourable to the work done by the Army Medical Service. Upon this followed the institution of Mr. Brodrick's committee for the reorganisation of the Army Medical Service, the personnel of which did not escape criticism. It got to work promptly and in a comparatively short space of time produced a document drawn with care and ingenuity, which was received with an outburst of adverse comment. Conditions were suggested by the committee with the laudable object of obtaining and maintaining a high standard of efficiency which were considered to be vexatious and which, it was thought, might impede in their working the careers of many officers. The document was none the less an honest attempt to show how the service could be placed on a satisfactory footing and many of the apprehensions which were expressed were groundless. One of the principal aims of the committee had been to make use of selection rather than of seniority when promoting an officer to a responsible post, another had been to bring the Army Medical Service into close relation with civil professional life, and a third to hold out inducements to men of scientific attainments to compete for commissions—surely all good aims. Examinations that were threatened resolved themselves, when looked at closely, into tests of a practical and clinical character, almost unavoidable if the principle of selection was to be followed. Six months later—i.e., in March, 1902—came the new warrant which followed the recommendations of Mr. Brodrick's committee fairly closely and under which the Army Medical Service now works.[2] The Royal Army Medical Corps is placed under the supervision of an Advisory Board, consisting of two officers of the service, two civilian surgeons and two civilian physicians appointed by the State, a representative each from the War Office and the India Office, a representative nursing matron, and the Director-General and Deputy Director-General. In this way the service should be managed so that good men may be obtained and kept. By the warrant the Director-General is given an increase of army rank and an increase of pay. The pay of medical officers is increased and provision is made for special pay and charge pay. The door is opened for scientific and professional study and for professional merit and distinction. By one new regulation a lieutenant on probation who at the time of passing the examination for admission to the Royal Army Medical Corps is holding, or is about to hold, a resident appintment in a recognised civil hospital, can be seconded for a period not exceeding one year, during which he is holding the appointment. While seconded he receives no pay from army funds but his service reckons towards promotion, increase of pay, gratuity, and pension. This is a distinct bid for a high class of candidate. And other regulations seek to insure the maintenance of a good standard. An officer is eligible for promotion to the rank of captain on the completion of three and a half years' service and to the rank of major on the completion of 12 years' service, "*provided that in each case he has previously qualified in such manner as may be prescribed by the Secretary of State.*" This regulation has seemed to some to foreshadow the examination in school work of men of mature years, much of whose time has been necessarily spent far away from books. But the belief has since grown that the subjects of examination would be as a rule of a thoroughly practical and clinical character, while it is clear that tests must be exacted if the principle of selection is to be followed. If an officer passes with distinction the examination qualifying for promotion to the rank of major the period of service required to render him eligible for the rank of major or lieutenant-colonel is reduced. In other words, promotion now comes largely by selection. Due provision is made for promotion to brevet rank and for distinguished service, and retirement at 20 years on £1 a day, one of the most attractive features of the service and one which was said to be in danger of alteration, is allowed to remain.

The Army Medical Service having laboured under many disadvantages and its work in South Africa having been unjustly belittled and discredited will require time to recover its popularity. But the present warrant seems to promise better things. It would be rash to prophesy more exactly, for the Advisory Board is still new to its work and can hardly be said to enjoy the confidence of the whole Service. Its functions are not as clear as they might be and there is difference of opinion as to the advisability of purely disciplinary and administrative matters being left to its jurisdiction. The selective principle has not had time to display its value, though the recent choice of a Director-General shows that it is intended to give the principle a thorough trial. Under Mr. Brodrick's abortive army scheme the Director-General of the Army Medical Service had a seat at the Army Council but Mr. Arnold-Forster's scheme relegates him to a place in the Quartermaster-General's department. Medical affairs would have had a much better chance of being understood if they were represented by a spokesman at the Army Council, and the exclusion of the Director-General from this body must be regarded as lamentable.

---

[2] The warrant will be found published in full in THE LANCET of March 29th, 1902.

(*To be continued.*)

PROPOSED CONFEDERATION OF LONDON MEDICAL SOCIETIES.

AN important meeting of members of the medical profession was held under the chairmanship of Sir WILLIAM S. CHURCH, President of the Royal College of Physicians of London, in the hall of the College, Pall Mall, London, on April 10th. The meeting was attended by over 200 medical men, many leaders of the profession in London being among them.

Sir WILLIAM CHURCH opened the proceedings with a statement in which he said that the attempt to unite the various medical societies of London had repeatedly been before the medical public but had hitherto always failed. In 1808 the Medical Society approached the Royal Medical and Chirurgical Society with the request that the two societies should form a society with a fresh name and a new habitation. That attempt failed owing to there being some doubt whether the proposed change of name and place might not invalidate the title that the societies had to certain properties. In 1850 the Pathological Society approached the Royal Medical and Chirurgical Society with a view to incorporation with the latter but the plan came to nothing owing to various minor details In 1860 a serious attempt was made to join the Medical Society with the Royal Medical and Chirurgical Society and the subject occupied the attention of the medical world for some 16 months, but after all the deliberations came to nothing. In 1867 the Medical Society again approached the Royal Medical and Chirurgical Society with the proposal that they should unite, but nothing came of that. In 1870 there was another attempt to join the two societies together and communications between them went on for nearly two months, but once more nothing took place. Then there was the attempt made by the late Sir Andrew Clark in which, though the societies themselves did not come into official communication, those interested met frequently at the house of Sir Andrew Clark and conferred together. Once again nothing came of these deliberations. Those who were interested in the present movement thought it best to propose that a new central body which he would call and speak of as the Royal Society of Medicine should be established and that all the existing societies should be regarded as subdivisions of it. The idea was that the existing societies should not lose their present individuality and that they should remain as societies embraced and covered by the wing of the Royal Society of Medicine. There could be no doubt whatever that great advantage would ensue if some such society were to be established which would embrace the whole of medicine and all the sciences affiliated to medical practice. Medicine of the present day, in consequence of the enormous advances in knowledge and of the necessity of now making use of special instruments, was necessarily split up into a large number of branches; and rightly enough each of those branches wished to have its own society for the furtherance of that portion of medicine in which the members of the society were especially interested. There seemed to be a certain amount of danger that those special subjects in medicine might get to be regarded as dissociated from general medicine. Anything that would tend to keep up the close [illegible] branc [illegible] All tl [illegible] prestige by being portions of the Royal Society of Medicine of the metropolis of the kingdom. The Fellows and associates of the proposed Royal Society would certainly enjoy a much greater advantage than was possible for them to have at the present time without increased expense. It was thought that there would have to be two grades in the society—namely, Fellows and Associates. The Fellows would join the Royal Society of Medicine on certain financial terms which would give them the right of being [illegible] societies. The As [illegible] preferred to be members of one or more sections of the society and who would have certain advantages and privileges by belonging to the Royal Society of Medicine, such as the use of the library and all the rooms of the society. If any such scheme was carried out it would be necessary to have more accommodation than there was at present at 20, Hanover-square, but those premises were capable of being enlarged to give a bigger meeting room and to provide smoking rooms and tea rooms. In fact, the premises would be much more comfortable than they were at the present moment. The Associates would therefore have certain rights, but as to what those would be he did not know himself, they must be left to be worked out by a committee. With regard to the question of what societies would be likely to join they might take as a working basis the societies that met at 20, Hanover-square and 11, Chandos-street. By that it must not be by any means implied that other societies were to be excluded, but it was merely wished to begin the discussion by taking those societies which seemed to be likely to join in the proposal. The societies referred to that met at 20, Hanover-square and 11, Chandos-street, were societies representing special branches of medicine, but there were also two societies which everyone had great regard for—he referred to the Harveian and to the Hunterian, which were general societies. He did not wish to imply that those two societies should be excluded but he only wished to point out that they were somewhat on a different footing to that of the special societies which met at 20, Hanover-square, and 11, Chandos-street. Continuing, Sir William Church observed that it seemed to him essential for the carrying out of the proposed scheme that the Medical Society, which was so important and powerful, should join in the movement. The Medical Society and the Royal Medical and Chirurgical Society were the only two societies which had any considerable amount of property and if such a combination as was suggested was made they would depend a good deal on the income which might be received from the property of the Medical Society to assist in maintaining the proposed Royal Society of Medicine. He thought it was desirable to face the fact that unless they found that the Medical Society was willing to consider the matter they did not see how they were to provide the extra accommodation and advantages proposed and at the same time to diminish the expenses of individual members. All the details of the necessary subscriptions and arrangements for the government of the society should be left for the consideration of a committee to be appointed at that meeting, which would have the duty of formulating a scheme to be laid before the medical profession later. Allusion had been made to the advantage of the proposed Royal Society having all the different sections of medicine under its wing, but attention should be drawn to the advantage to be derived by British medicine from the proposal. The separate sections of the society would receive and consider their own communications as each thought proper and publish monthly all the papers, while the parent society would with a strong publishing committee select from the communications made to all the various societies under its wing and publish them as the transactions of the Royal Society of Medicine, and such transactions would form a most valuable addition year by year to medicine and would be representative of British medicine. Sir William Church concluded by saying that he ha [illegible] communications all from men of note and [illegible] of most of the societies mentioned, all of them favourable to the idea of confederation, though of course all were not unanimous as to the exact scheme. Sir John Burdon

Sanderson, President of the Pathological Society, had written to say that he was strongly in favour of such a combination of societies being made some years ago and he was still in favour of the proposal. Several gentlemen who did not hold official positions in the various medical societies had expressed the hope that something would come out of the present meeting. Sir William Church was then handed a telegram which was found to be from Mr. J. Tweedy, President of the Royal College of Surgeons of England, regretting his inability to be present at the meeting.

Sir FREDERICK TREVES proposed the following motion:—

[illegible]

He said that the amalgamation proposed would have obvious advantages in many directions. In the first place it would have the great advantage of convenience to have all the branches of medicine represented under one roof and it would be also economical. At the present time each society had its own management, its own premises to provide, and in many cases its own library. The money expended by these various [illegible] if the [illegible] must [illegible] able that the science of medicine should be able to face the scientific world as a coherent whole. There was so great [illegible] in the various branches of medicine which was very desirable and would secure a stronger position for the science of medicine as a science. The proposed society would not, he imagined, concern itself with politics or medical ethics but would be devoted to the science and art of medicine in the widest sense of the term. In his opinion, those who founded the Medical Society and the Royal Medical and Chirurgical Society intended to include all medicine and surgery in their schemes. He pointe[illegible] must involve sacrific[illegible] of sentiment. Sir [illegible] appeal for the proposal.

Sir THOMAS SMITH, in seconding the motion, said that he believed that the proposed amalgamation would be greatly to the benefit of all concerned. In 1870 he was occupied with Sir Geo[illegible] to carry out an amal[illegible] He knew some of the [illegible]d if the [illegible] proposal.

Mr. JOHN LANGTON said he wished it to be understood that he was speaking merely as a Fellow of the Medical Society and not as its President.

Sir WILLIAM CHURCH here observed that no official communications had passed between him and any society, therefore they were all expressing at that meeting their own individual opinion and nothing said would be taken as representing the feeling of any society.

Mr. LANGTON, continuing, said that he was in a great measure in accord with what had fallen from Sir Frederick Treves and Sir Thomas Smith. The difficulties would be great, for it meant that there would be much giving and little taking. On the whole, however, it would be for the progress of medicine and surgery and for their definite advancement. The societies should not ask what shall we get and what shall we lose but should consider if the proposal was for the advancement of science and in that case the scheme would be for the good of all. The proposal would prevent the great over lapping of work in the societies which might be avoided.

Dr. F. J. MCCANN suggested that the title should be the Royal Academy of Medicine instead of the Royal Society of Medicine.

Sir WILLIAM CHURCH said that it would be open to the committee which was to be formed for the consideration of the scheme to suggest what the title should be.

Dr. MCCANN thereupon withdrew his suggestion.

Dr. C. THEODORE WILLIAMS said that financially the scheme would be a great thing for the junior members of the rofession, because instead of being mulcted in some eleven guineas a year they would get all the advantages for three or four guineas. If the proposal was carried out they would be more in the position of some of the foreign academies of medicine.

Dr. T. GLOVER LYON, senior honorary secretary of the H[illegible] to say that the proposed [illegible] the Hunterian Society [illegible]

Sir R. DOUGLAS POWELL said that he did not think it had entered into the minds of those who proposed the union of the medical societies to suggest more than the union of the central societies. He thought that it would be a disaster to the medicine of London [illegible] which were so valuable in [illegible] in their neighbourhood and [illegible] special subjects in their profession, were to be merged into one society. In regard to the point of economy, roughly speaking something like £16,000 a year was spent by medical men on the central societies in London. He considered that under the new scheme the work would be more economically carried on.

Mr. D. H. GOODSALL said that the scheme should be so arranged that no society should feel that it had been snuffed out. The more the scheme was considered the more it would be clear what a great saving would be secured.

The motion as proposed by Sir FREDERICK TREVES was then put to the meeting and carried unanimously.

Sir WILLIAM BROADBENT *moved the following proposition*:—

> [illegible] Medical, Royal Medical and Chirurgical, [illegible]ties be severally invited to appoint two [illegible] President of the Royal College of [illegible] the Royal College of Surgeons, and five [illegible] which shall (1) make such inquiries [illegible]mit a scheme of union to the various [illegible]

He at once suggested a slight modification of the motion which he had read to the effect that the Medical Society and Royal Medical and Chirurgical Society, as the oldest societies and as having property and libraries, should [illegible] on the committee. Further, [illegible] Society and Clinical Society [illegible] they each should have one only and the Obstetrical Society and the Epidemiological Society should each have a representative. It would be seen that if the suggestion which he had made was followed the number of official representatives on the committee would be the same but the representation would be on a somewhat broader basis. It was extremely important to recognise that to secure the success of the scheme a great wave of general opinion was necessary in order to carry [illegible] hitherto [illegible] re than a [illegible]n which [illegible] jects would be prevented. Not only would time be economised but the subjects discussed would be more efficiently and thoroughly treated. He would prefer that the title of the society should be the Royal Academy of Medicine. In regard to the local outlying societies of which Sir R. Douglas Powell had spoken he considered that they also ought to be invited to coöperate in the movement. He admitted that it would be a great misfortune to interfere with the efficiency of these local societies but he thought that they would benefit by becoming connected with the scheme.

[illegible] in seconding the motion, said [illegible] to snuff out any societies. He [illegible]ve a library if the scheme was [illegible] as they did not possess at the present moment. In his opinion the benefits to be derived from the proposed union were extraordinary and unlimited.

Dr. WILLIAMS said that the other societies interested in the matter should also be represented on the committee, otherwise how could they put forward their views? The committee must be large and, speaking for himself, if he [illegible] Medical Society and the Royal Medical and Chirurgical Society were the societies that possessed property it would be better to ask those two societies to appoint delegates and let them arrange for the representation of the other societies.

Sir FELIX SEMON suggested that the two societies possessing property should be asked to send two or three delegates to the committee and that the rest of the committee should be formed by all the presidents of the societies who were asked to form the scheme.

Sir WILLIAM CHURCH suggested that the best way out of the difficulty would be to appoint a committee consisting of two representatives from the Medical Society, two from the Royal Medical and Chirurgical Society, which were really the societies that would bring in the money, one representative each from any other societies that wished to join in the scheme, and the Presidents of the Royal Colleges. This committee should be charged with the duty of making such inquiries as might be necessary and submitting a scheme of union to the various societies for their consideration.

This proposition was then put to the meeting by Sir WILLIAM CHURCH and agreed to unanimously.

The appointment of honorary secretary to the committee was then considered and Dr. Arthur C. Latham was elected.

Dr. JOHN FAWCETT then moved

That a general meeting of the societies concerned be convened in July next, if possible, to receive the report of the committee.

This was seconded by Mr. H. S. PENDLEBURY and carried.

The meeting terminated with a vote of thanks to Sir William Church for presiding, which was moved by Mr. A. WILLETT and seconded by Sir FELIX SEMON.

THE CERTIFICATION OF SENILE DEMENTIA AS LUNACY OR IMBECILITY.

THE patients under the care of the Metropolitan Asylums Board include several thousands of mentally defective persons who are chargeable to the various London Poor-law authorities but are for obvious reasons ill-fitted for retention in either the existing workhouses or pauper infirmaries. Their condition being usually chronic or congenital is necessarily irremediable and they are best dealt with not by certification as lunatics but by simple admission to specially established asylums for imbeciles. The existence of these institutions has much facilitated the work of local Poor-law authorities who have, in fact, been tempted to make too liberal a use of the facilities thus provided and to enlarge the accepted definition of imbecility, by causing it to include the failure of the mental faculties incidental to old age or to general exhaustion from chronic disease. The natural consequence is that the medical superintendents of the imbecile asylums protest against the admission of moribund persons who ought on the grounds both of humanity and expediency to have been retained in the local institutions. The various aspects of the question were discussed at some length by the Metropolitan Asylums Board at a meeting held on Feb. 18th. The subject came up for consideration in connexion with the annual report for 1904 of the imbecile asylum at Caterham in Surrey by Dr. P. E. Campbell, who had drawn attention to the "increasing practice of certifying as lunatics quiet, harmless, mostly senile cases," a practice "much to be deprecated and in a great measure accountable for the recorded yearly increase in the number of pauper lunatics." The medical superintendents of the other asylums having been invited to furnish their views on this subject had all agreed with the remarks of Dr. Campbell. The asylums committee of the Board thought that many patients who had been sent to Tooting Bec Asylum should have been retained in the workhouse infirmaries. On humanitarian grounds alone, the committee stated, that course would seem to be a proper one, for it involved neither the removal of the patients to distances which rendered visitation by friends a matter of difficulty, not to speak of expense, nor the possible injury to their families by the stigma of insanity. The committee recommended that the attention of the Local Government Board should be called to the matter with an intimation that the managers would be glad if they could be furnished with the views of the Board on the subject. It was urged during the discussion which followed that there should be one authority in London for dealing with all cases of imbecility and insanity and that receiving homes should be established where the cases could be diagnosed and sent to the proper institutions.

Speaking generally, we are in agreement with the views expressed by the medical superintendents of the imbecile asylums. That the complaint as to the unnecessary certification of individuals exhibiting mental symptoms differing but little from those of ordinary senility is justified will be admitted, we believe, by all with practical knowledge of institutions for the insane. If the asylums of the Metropolitan Asylums Board have reasons to protest in this matter, so also have the county asylums. Doubtless many elderly persons are sent to asylums with mental symptoms which cannot be regarded as pertaining to physiological old age but which are beyond question pathological. Such persons are often excessively difficult to manage by reason of their restlessness and however unwelcome these cases may be in asylums it cannot be expected that they should be cared for by their friends or even in workhouses adequately equipped for dealing with cases of imbecility and mild insanity. These are very different from the quiet, harmless cases referred to above whose care does not require the elaborate equipment of a modern asylum. It is said that the practice of disposing of these cases by sending them to asylums for the insane is increasing and in this connexion certain statistics given in the last report of the Commissioners in Lunacy are interesting. A comparison is therein made between the statistics of the population at the census of 1891 and that of 1901 and those of institutions for the insane for England and Wales. The figures are grouped under two heads, as affecting persons who had attained the ages of 20 to 54 years in one group and those aged 55 years and upwards in the other. The statistical facts gathered, which refer to about four-fifths of the total (known) insanity, justify the inference that, as regards those cared for in institutions, "the rate of increase in numbers, both of those in residence and those admitted, when contrasted with the total number of persons living at each term, has been much smaller amongst those of ages 20 to 54 than amongst those above the latter age. Indeed, if comparison with the actual rate of increase of the population in the ten years be permissible, the rate of increase of the ratio of the insane to population is seen to be below the foregoing rate in the younger group but above it in the older."

It may be contended that the consignment of their relatives to asylums on an increasing scale argues a greater confidence in these institutions on the part of the public; but there is another and less agreeable explanation to be found in the possible diminution of filial respect and sense of duty. When we look round the wards of an asylum and note cases of quiet senile dementia, those admitted as such and those which have after long residence become such, the question arises whether, in less strenuous times, many of these would not have been cared for with solicitude and efficiency in the homes of their children. In default of home care asylums could be relieved of such cases by workhouses or by the system of boarding out in private care. The proposition said to have been brought forward at the meeting of the Metropolitan Asylums Board respecting the desirability of having one authority in London for dealing with all cases of insanity and imbecility commends itself to common sense.

SECURITY OF TENURE FOR MEDICAL OFFICERS OF HEALTH.

AMONGST the Bills which may shortly be brought before Parliament is the Public Health Bill, of which Dr. C. F. Hutchinson has charge. This is a Bill to secure to all medical officers of health and sanitary inspectors similar security in their tenure of office to that enjoyed by Poor-law medical officers and metropolitan medical officers of health—that is to say, such officers shall be removed only by, or with the consent of, the Local Government Board. Periodically there occurs some glaring example of a medical officer of health being cast adrift by the local sanitary authority, sometimes through a too conscientious observance of his duties by that officer, and sometimes from the advocacy of certain measures which it is feared will increase the rates, or which may injuriously affect certain vested interests of his masters, the district councillors. The most recent illustration of the precarious nature of the appointments held by medical officers of health is afforded by the action of the Havant rural district council. The district of this council is a large straggling one, consisting of Hayling Island and various small villages, with an area of over 10,000 acres and a population of about 4500. The present medical officer of health, whose remuneration is the magnificent sum of £30 per annum, has held the appointment for over 26 years, during which period he has to [illegible] conscientious [illegible] ver, has appa- [illegible] Havant rural [illegible] l, without any complaint being formulated, these bucolic legislators decided that the fitting reward for over a quarter of a century's faithful service was sudden dismissal. A certain furtiveness, or it may be modesty, even then characterised their action, for no intimation whatever was given to the medical officer that it was intended to dispense with his services; the first notice that this gentleman received was seeing the advertisement for a medical officer of health in the local press. There had never been any question of neglect of duty or incompetence in its performance to warrant the advertisement.

The action of the council is the more instructive inasmuch as Mr. A. Stewart Norman, the medical gentleman in question, is well known in the south of England in connexion with sanitary matters and is, in fact, at the present time President of the southern branch of the Incorporated Society of Medical Officers of Health. Further, when already holding the appointment and though busy at the same time with private practice, Mr. Norman, in order to be the better qualified to carry out his duties, devoted considerable time to the study of hygiene, and in 1893 obtained the diploma in public health at the University of Cambridge. It is with considerable pleasure that we have the satisfaction of recording that in this particular instance the action of the council in attempting to slight its medical officer has recoiled on itself, for such is the respect in which Mr. Norman is held by the public generally, and his professional brethren in particular, that no medical man in the district could be induced to send in an application; the council had, therefore, to the benefit of the district, though doubtless to its own mortification, to re-elect Mr. Norman to the post he has so well filled. Voters in rural districts are proverbially apathetic, but it will be indeed strange if those district councillors who are responsible for the recent treatment of Mr. Norman do not have the contemptibility of their action brought home to them when next applying for re-election. Although in the above instance the medical officer of health did not suffer a grave injustice, the important fact to remember is that it was not from any want of will on the part of the local sanitary authority; it was prevented solely by the loyalty of medical men in the neighbourhood. It is more than likely that had the salary attached to the appointment been a large one and had it been advertised in the medical press so as to reach a large number of medical men who were unaware of the true state of affairs numerous applications would have been received and in all probability Mr. Norman would have been dismissed.

Not once but many times has attention been drawn in THE LANCET to the urgent necessity for fresh legislation to govern the appointment of medical officers of health. That the officer who is responsible for the measures to be taken fc [illegible] sease sl [illegible] ugly bl [illegible] tion of this country. Doubtless the reason that so unsatisfactory a state of affairs has been allowed to exist so long is ignorance on the part of the public; the latter, if ever it gives the matter a thought, seems to hold the belief that medical officers can only be dismissed with the consent of the Local Government Board—a totally erroneous idea that has probably arisen from a confusion of these appointments with those of medical officers under the Poor-law Acts. When medical officers were appointed under the Poor-law it was felt that the power of their dismissal should not be vested in boards of guardians and legislation was enacted accordingly. Strangely enough, no such protection has been afforded to medical officers of health, yet the latter are far more likely to suffer injustice than are the former. Indeed, if a medical officer does his duty in a rural district he is morally certain, sooner or later, to offend some of his councillors, with the result that he is dismissed and a more complacent officer sought.

Everyone must feel that the time has come when the perpetration of such a flagrant act of injustice as was attempted at Havant should be put beyond the power of local authorities. At Havant, it is true, beyond the slight put upon the medical officer no great harm has resulted. This, however, cannot be said of similar occurrences that have been recorded in other parts of the country where medical officers have lost their appointments solely from their refusal to sacrifice their sense of duty to their own personal aggrandisement. Leaving out of consideration altogether, moreover, the question of injustice to the medical officer there is the still stronger argument that the public can have no right to expect that the requirements of the Public Health Acts will be efficiently administered if medical officers always have to consider whether the advancement of certain needed sanitary reforms will not injuriously affect their personal relations with their council. For these reasons, therefore, both in the interest of the profession and in that of the public, the Public Health Bill of Dr. Hutchinson may be heartily commended to the earnest consideration of Members of Parliament and it is to be hoped that ere long a fundamental alteration will be effected in the very anomalous conditions under which medical officers of health now hold their appointments.

THE BELGRAVE HOSPITAL FOR CHILDREN.

A MEETING of medical men practising in the neighbourhood of the Belgrave Hospital for Children, Clapham-road, London, was held at that hospital on April 11th. The meeting was convened by the honorary medical staff of the Belgrave Hospital for Children in order to discuss certain proposals with the medical men in the district, as both the committee of management of the hospital and the medical staff were anxious that the work of the hospital should be carried on in such a manner as not to prove injurious to medical men practising in the district. The invitation to the meeting was sent out to about 150 medical men and the medical staff stated that it was their wish that only those patients should be treated at the hospital who, by reason of their poverty or the nature of the illness, were suitable subjects for hospital relief. Further, they were anxious that the hospital should be of advantage to the medical men in the district. The following gentlemen attended the meeting in response to the invitation of the medical staff: Dr. J. W. J. Oswald, Mr. H. H. Norton, Mr. A. J. McNickle, Dr. Benjamin Jones, Mr. W. E. Pain, Dr. Joseph J. O. Constable, Mr. J. O. Constable, Mr. M. S. Duke, Mr. J. G. Glasgow, and Mr. A. C. Robinson. The members of the medical staff who attended to confer with the medical men in the district were Dr. W. Ewart, Dr. E. Cautley, Mr. N. Bishop Harman, Mr. D. J. Armour, and Mr. H. Lett.

The proceedings commenced under the chairmanship of Dr. EWART with a discussion on the suggestion put forward by the medical subcommittee of the medical staff that a local medical society should be formed by the medical practitioners in the neighbourhood of the hospital. After the subject had been debated thoroughly it was agreed that the matter should be postponed until some future date when the views of the local practitioners concerned could be accurately ascertained.

In consequence of Dr. Ewart having to leave Dr. CAUTLEY took the chair and explained that the next business on the agenda paper was the subject of out-patients It was agreed that not more than 20 new surgical cases and 20 new medical cases should be seen on each day by the medical officer in attendance. In regard to the selection of cases preference was to be given to those most seriously ill and to cases referred to the hospital by medical practitioners.

A prolonged discussion took place in regard to the management of the out-patient department and it was finally decided that out-patients living within a radius of two miles from the hospital should only be admitted, except in the case of urgent illness or accident, on the presentation of a card signed by a medical man. It was also arranged that similar cards for admittance should be issued to the Charity Organisation Society and to almoners. Dr. Cautley at this stage of the proceedings pointed out that the occurred in Glasgow, three in Paisley, and three in Greenock. The deaths from diarrhœa, which had been eight in each of the two preceding weeks, rose to 20 last week and included ten in Glasgow, four in Aberdeen, three in Edinburgh, and three in Dundee. The fatal cases of measles, which had been ten, six, and five in the three preceding weeks, rose again last week to 13, of which eight were registered in Glasgow and four in Edinburgh. The deaths from diphtheria, which had been eight, ten, and five in the three preceding weeks, were again five last week, and included two in Glasgow and two in Edinburgh. The fatal cases of "fever," which had been three, one, and four in the three preceding weeks, further rose last week to five, of which two were recorded in Glasgow and two in Aberdeen; in each of these towns one of the two deaths from "fever" was a case of typhus. The deaths referred to diseases of the respiratory organs, which had been 140, 133, and 105 in the three preceding weeks, rose again to 119 last week, but were 19 below the number in the corresponding period of last year. The causes of 15, or nearly 3 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 23·8, 22·4, and 24·9 per 1000 in the three preceding weeks, further rose to 25·5 per 1000 during the week ending April 8th. During the past four weeks the death-rate has averaged 24·2 per 1000, the rates during the same period being 15·4 in London and 16·8 in Edinburgh. The 185 deaths of persons belonging to Dublin registered during the week under notice were four in excess of the number in the preceding week, and included five which were referred to the principal infectious diseases, against eight, seven, and eight in the three preceding weeks; of these, two resulted from diarrhœa, and one each from diphtheria, from whooping-cough, and from "fever," but none from small-pox, measles, or scarlet fever. These five deaths were equal to an annual rate of 0·7 per 1000, the death-rates last week from the principal infectious diseases being 1·3 in London and 1·5 in Edinburgh. The 185 deaths in Dublin last week included 31 of children under one year of age and 57 of persons aged 60 years and upwards; the deaths both of infants and of elderly persons exceeded the respective numbers recorded in the preceding week. Seven inquest cases and two deaths from violence were registered; and 73, or nearly two-fifths, of the deaths occurred in public institutions. The causes of 10, or more than 5 per cent., of the deaths registered in Dublin last week were not certified.

VITAL STATISTICS OF LONDON DURING MARCH, 1905.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious disease it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 6·0 per 1000 of the population, estimated at 4,684,794 persons in the middle of the year. In the three preceding months the rates had been 6·1, 5·8, and 5·9 per 1000 respectively. The rates were considerably below the average in Paddington, Kensington, Chelsea, the City of Westminster, and Southwark; while they showed the largest excess in Stoke Newington, Bethnal Green, Stepney, Wandsworth, Lewisham, and Woolwich. The prevalence of small-pox last month exceeded that in any other recent month; of the 25 cases notified during March, 12 belonged to Stepney, six to Camberwell, two to Hackney, and two to Greenwich. The Metropolitan Asylums hospitals contained 20 small-pox patients at the end of last month, against 17, 15, and 15 at the end of the three preceding months; the weekly admissions averaged four, against four, one, and three in the three preceding months. Scarlet fever showed a slightly increased prevalence compared with that in the preceding month; among the various metropolitan boroughs this disease was proportionally most prevalent in Hampstead, Stoke Newington, Shoreditch, Bethnal Green, Wandsworth, Lewisham, and Woolwich. The number of scarlet fever patients under treatment in the Metropolitan Asylums hospitals, which had been 2349, 2067, and 1941 at the end of the three preceding months, had risen again to 1997 at the end of last month; the weekly admissions averaged 272, against 233, 209, and 231 in the three preceding months. The prevalence of diphtheria last month showed a considerable decline; the greatest proportional prevalence of this disease occurred in Stoke Newington, Hackney, Bethnal Green, Stepney, Poplar, and Woolwich. The Metropolitan Asylums hospitals contained 788 diphtheria patients at the end of last month, against 800, 836, and 837 at the end of the three preceding months; the weekly admissions averaged 98 against 99, 115, and 118 in the three preceding months. Enteric fever was slightly less prevalent than it had been during the preceding month; among the various metropolitan boroughs this disease showed the greatest proportional prevalence in Paddington, Holborn, Stepney, Lewisham, and Camberwell. The number of enteric fever patients in the Metropolitan Asylums hospitals, which had been 237, 134, and 105 at the end of the three preceding months, had declined to 68 at the end of March; the weekly admissions averaged 11, against 22, 17, and 13 in the three preceding months. Erysipelas was proportionally most prevalent in Shoreditch, Bethnal Green, Stepney, Camberwell, and Deptford. The 25 cases of puerperal fever notified during the month included four in Fulham, three in Islington, and two each in Hammersmith, Shoreditch, Battersea, and Wandsworth.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various metropolitan boroughs, the deaths occurring in public institutions having been distributed among the several boroughs in which the deceased persons had previously resided. During the five weeks ending April 1st the deaths of 6977 persons belonging to London were registered, equal to an annual rate of 15·5 per 1000; in the three preceding months the rates had been 18·4, 17·0, and 16·4 per 1000. The lowest death-rates in London last month were 9·9 in Hampstead, 12·2 in Woolwich, 12·9 in Wandsworth, 13·6 in Hammersmith, and 13·8 in the City of Westminster and in Stoke Newington; the highest rates were 18·0 in Stepney, 18·1 in Holborn, 18·4 in St. Marylebone, 19·1 in Shoreditch, 19·2 in Southwark, 19·5 in the City of London, and 19·8 in Finsbury. The 6977 deaths from all causes in London last month included 532 which were referred to the principal infectious diseases; of these, two resulted from small-pox, 153 from measles, 54 from scarlet fever, 58 from diphtheria, 197 from whooping-cough, 15 from enteric fever, and 53 from diarrhœa. No death from any of these diseases was recorded last month in the City of London; among the metropolitan boroughs they caused the lowest death-rates in Paddington, the City of Westminster, Hampstead, Lambeth, Battersea, Deptford, and Woolwich; and the highest rates in Fulham, Hackney, Shoreditch, Bethnal Green, Stepney, Poplar, and Southwark. The two fatal cases of small-pox included one in Hackney and one in Stepney. The 153 deaths from measles were less than half of the corrected average number; the greatest proportional mortality from this disease occurred in Hackney, Shoreditch, Stepney, Bermondsey, Wandsworth, and Lewisham. The 54 fatal cases of scarlet fever were eight in excess of the average number in the corresponding periods of the ten preceding years; this disease was proportionally most fatal in Chelsea, Hackney, Finsbury, Shoreditch, Stepney, and Bermondsey. The deaths from diphtheria numbered 58 last month, against a corrected average of 167; the highest death-rates from this disease were recorded in Bethnal Green, Stepney, Poplar, Southwark, and Woolwich. The 197 fatal cases of whooping-cough were 94 fewer than the corrected average number; this disease showed the highest proportional fatality in Kensington, Fulham, Chelsea, Hackney, Shoreditch, Bethnal Green, Southwark, and Camberwell. The 15 deaths from "fever" showed a decline of 21 from the average number in the corresponding periods of the ten preceding years and included three in Stepney and two each in Kensington, St. Marylebone, and Islington. The 53 fatal cases of diarrhœa were 15 below the corrected average number; among the various metropolitan boroughs this disease was proportionally most fatal in Fulham, the City of Westminster, Bethnal Green, Stepney, and Poplar. In conclusion, it may be stated that the aggregate mortality in London last month from the principal infectious diseases was more than 45 per cent. below the average.

Infant mortality, measured by the proportion of deaths among children under one year of age to registered births, was equal to 116 per 1000. The lowest rates of infant

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeons: H. J. Hadden to the *London;* A. F. Harper to the *Renown;* A. G. Wildey to the *Ramillies;* E. H. Hodnet de Courtmacsherry to the *Powerful;* and W. E. Home to the *Hannibal.* Staff Surgeons: A. H. H. Vizard to Bermuda for service in Ireland Island and Dockyard; P. V. Jackson to the *Latona;* E. T. Meagher to continue to be lent to the *Ramillies;* S. H. Birt to the *Indefatigable;* and F. Bradshaw to the *Edgar.* Surgeons: H. A. Kellond-Knight to the *London:* E. Arkwright to the *Sentinel* on commissioning; P. W. MacVean to the *Flora*; A. F. Mackay to the *Ringdove* on commissioning; N. B. V. Jacob to the *Sapphire II.*, lent temporarily; G. Moir to the *Research*, lent for summer season; A. R. Davidson to the *Triton*, lent for summer season; S. H. Facey to the *Albion;* N. H. Harris to the *Pembroke:* and F. H. Nimmo to Haslar Hospital.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel J. Hoysted, Army Medical Staff (retired), is to proceed to Derby for duty. Lieutenant C. R. Tichborne, R.A.M.C. (Militia), assumes medical charge of troops and Non-Dieted Hospital, Kildare. Major F. W. Begbie is appointed Secretary and Registrar of the Military Hospital at Millbank. Captain A. M. MacLaughlin is posted to Belfast for duty.

Lieutenant-Colonel P. J. Dempsey is placed on retired pay (dated March 28th, 1905). Captain W. J. P. Adye-Curran, from half-pay, to be Captain (dated March 23rd, 1905). Lieutenant J. A. Longley resigns his commission (dated April 8th, 1905).

THE COURSE OF INSTRUCTION AT HASLAR.

The course of instruction for Surgeons R.N. at Haslar Hospital terminated on April 6th, when the prizes were distributed by Vice-Admiral Sir Charles Drury, K.C.S.I., Second Sea Lord, who was accompanied by the Commander-in-Chief at Portsmouth and by the Medical Director-General of the Navy. Luncheon was served in the officers' mess prior to the distribution of the prizes and Sir Charles Drury gave a short address to the newly commissioned surgeons. The gold medal was gained by Surgeon L. F. Cope (St. George's Hospital), the microscope by Surgeon L. C. Hunt (St. George's Hospital), and the silver medal and books by Surgeon H. M. Braithwaite (University of Durham). The names of the candidates with the combined marks gained at the entrance examination and at the Haslar course are subjoined.

THE 1ST CADET BATTALION OF THE ROYAL FUSILIERS (CITY OF LONDON REGIMENT).

Writing from the Hampstead headquarters of the 1st Cadet Battalion the Royal Fusiliers (City of London Regiment), the commanding officer, Lieutenant-Colonel Frank Sheffield, wishes to draw attention to the opening ceremony which has been fixed by the Prince of Wales, colonel-in-chief of the Royal Fusiliers, for Monday evening, May 15th. In the course of a careful preliminary inspection of these headquarters His Royal Highness was pleased to express unqualified "approval of their extent, architectural appearance, and general completeness, in which respect they are unsurpassed by any similar buildings in the metropolis." The battalion is entirely dependent upon voluntary subscriptions which may be sent to Lieutenant-Colonel Sheffield at the headquarters, Pond-street, Hampstead, N.W.

NAVAL MEDICAL SUPPLEMENTAL FUND.

At the quarterly meeting of the directors of the Naval Medical Supplemental Fund, held on April 11th, Sir J. Dick, K.C.B., being in the chair, the sum of £50 was distributed among the several applicants.

THE AMERICAN NURSES IN JAPAN.

The *Century Magazine* for the present month contains an article by Mrs. Anita Newcomb McGee, M.D., descriptive of what is termed an international episode afforded by the proceedings and the experience of the American corps of nurses in Japan. A special interest is lent to the paper by the light that it throws upon the nature and the working of the medical, nursing, and hospital systems in that country under the strain and the conditions of a war of unparalleled magnitude. Dr. Anita McGee took a party of well-trained American nurses to Japan in 1904 for six months' uncompensated service. They were received as guests of the Japanese nation and the object of their visit very naturally roused the sentiment and enthusiasm of the people. In the present war Hiroshima, in Western Japan, although not the seat of the Japanese Government, is the principal place of military activity. The policy of the Army Medical Department has been to establish its great base hospital there. At Hiroshima the most serious surgical work is done and, in the words of Surgeon-General Fujita, "except for the smoke and noise of battle Hiroshima is the front." The hospital consisted in October of eight divisions of different sizes with a total capacity of about 14,000 beds, or 17,000 if closely crowded. These divisions are located on what was previously vacant land in different parts of the city outskirts. The division for contagious diseases, including both typhoid fever and dysentery, is one of the smallest, with only 500 beds. The wards are one-storey wooden structures on the pavilion plan and usually for 60 or 70 beds each. For officers and critical cases certain wards are partitioned into small rooms. Several train-loads of patients leave Hiroshima daily, so that the wards are scenes of perpetual change. "The Red Cross Society of Japan is probably, all things considered, the finest organisation of the kind in the world." It has now nearly 1,000,000 members, an excellent relief organisation, and large funds. It is the ally and assistant of the medical officers and altogether subordinate to their orders. The nursing in the field and part of that on hospital ships are done by men. The training of the female nurses is good; it is military throughout and a large proportion of women undertake it primarily as an act of patriotism. One of the things which seems greatly to have struck the American nurses was the strength and endurance of these seemingly delicate and frail Japanese women. Nurses were on duty at the Hiroshima hospital for 28 hours continuously. "All through the hot summer those dear little women were in their wards from eight one morning till noon the next day, followed by a third day of eight hours, and beginning on the fourth another long period. Like all Japanese, they drank hot tea at any hour but they took scarcely 15 minutes to eat their light cold meals. They thought nothing of carrying a man on their backs, just as in childhood they had probably carried their little brothers." As regards obedience to discipline, cheerfulness, habitual kindness, willingness to serve, and an unfailing urbanity in little things, the female Japanese nurses are not easily to be surpassed.

THE WAR IN THE FAR EAST.

The great interest felt everywhere in the present stupendous war has been altogether translated for the time being from the land to the sea and as to what is to be the outcome of the next naval operations which may apparently occur at any moment and may be attended with momentous results. Should the Japanese fleet be defeated so as to entail the loss on its part of command of the sea it is obvious that the whole complexion of the war will be altered, while, on the other hand, if Admiral Rojdestvensky's fleet be defeated it may, and not improbably will, lead to an end being made to this terrible war by terms being proffered on the part of Russia in order to secure peace—a result devoutly to be wished in the cause of humanity. Meanwhile there is still some uncertainty about the Russian fleet and as regards the whereabouts of the Japanese fleet the secret is being well kept, absolutely nothing being allowed to leak out on the part of the Japanese authorities. We have for the first time since the battle of Mukden some trustworthy news as to the belligerent armies in Manchuria. These are in touch and intelligence may be any day received of the fighting being renewed in that direction. According to a telegram from Moscow sent by the special correspondent of the *Standard* an unfortunate Red Cross scandal has just occurred there. Two princes of the Urussoff family and two other nobles were to have been tried there on charges of fraud in connexion with the Russian Red Cross Society. None of them, however, entered an appearance. One of the princes was absent on duty in the Far East while the other had fled abroad and their two alleged accomplices were nowhere to be found.

Probably a unique case, says the *Novosti*, is that of M. Heiman of Riga, who has three sons serving in the active army as surgeons. They were called up singly from the youngest to the eldest in February, May, and October last year respectively. The second has been decorated for the part which he took in the fight at Liaoyang.

The Yaroslav hospital detachment lost all its material, valued at £400, at the battle of Mukden, whilst the losses of the Kharkoff detachment at the same battle are said to be £1500.

It has been decided that from July 1st next, until further orders, all staff, medical, and departmental officers serving at home or abroad (except India) shall, in common with regimental officers, have the option of drawing their pay either through the agents or the local accountant or paymaster. Servant allowance will continue to be drawn in the same manner as the pay, but field allowance and allowances in lieu of forage, stabling, lodging, and fuel and light will always be drawn through the local accountant.

Surgeon-General A. H. Keogh, C.B., Director-General A.M.S., has intimated to general officers commanding that it is considered desirable that matrons or acting matrons should keep a permanent record of all the sisters and staff nurses of the Nursing Service and also of the Army Nursing Service Reserve members who are serving under them in each hospital.

Defective colour vision, it has been decided, shall no longer disqualify candidates for commissions in the army.

"Audi alteram partem."

THE TEACHING OF HYGIENE IN ELEMENTARY SCHOOLS.

To the Editors of THE LANCET.

SIRS,—In a leading article in THE LANCET of April 8th, p. 939, you deal with the present much-debated subject of a syllabus defining the scope of the teaching of hygiene in elementary schools. As one who attended the recent School Hygiene Conference, which met under the auspices of the Royal Sanitary Institute, I was impressed with the circumstance that opinions differed widely upon this subject, according as to whether the speaker was a physiologist, a public health official, or an educationist, and, generally speaking, an unduly high standard of knowledge was favoured. It appears to me that in the whole scheme of teaching hygiene in elementary schools the fact must never be lost sight of that, *from the broadest point of view*, it is only simple and essential matters that require to be taught and that any scheme aiming at more than this will certainly fail to realise the best results. Moreover, if the subject is to be gone into as deeply as many advocate it would demand a greater share of the already congested school time table than educationists are prepared to bestow. Of course, the distinction must be drawn between what the teacher should know and what the scholar should be taught, but in drawing up a detailed syllabus for the latter we have only to ask ourselves at every step, Is it essential that he or she should know this? Is it knowledge which he or she can apply? To take an example, Is it necessary to teach the scholar the structure of the lungs and the mechanism of respiration in order to impress upon him the importance of fresh air, or is it sufficient to base the teaching on the results of common experience and the simplest possible expression [illegible] the simple and practical devices by which the best results may be obtained in living and sleeping rooms? Surely it is not necessary (although the Board of Education would appear to suggest that it is) that while making reference to the vital necessity of the oxygen in the air the issue in the child's mind should be confused by any allusion to the injurious properties of oxygen *under artificial conditions*. The facts which it is necessary to teach and which would (if generally practised) reduce the sum of preventable misery, suffering, and death very considerably could be incorporated in a short syllabus and the physiology necessary to explain them and to make their importance realised can always be adequately set out in simple non-technical language. The scientific principles involved may be very largely left to the students who attend evening continuation classes, for many of them hardly appeal to the intelligence of the child under 14 years of age.

In short, the instruction must deal with the most easily understood, the cheapest, and the most practicable means of translating sanitary precepts into practice. The conduct demanded of the scholar will constitute the hygienic training necessary, and the school buildings and fittings should, so far as possible, be made to illustrate all necessary hygienic observances. But the *training in the observation of sanitary* precepts is a form of moral training, and if the home influences are antagonistic to those of the school the home influence will often prevail. Therefore, a dirty and neglected child indicates the necessity of attempting to do something to improve the parents. Simple and elementary as the teaching must be, its range must necessarily be a comprehensive one and every female child should be taught the elementary facts of suitable selection of food, cooking, and infant rearing. The Board of Education is certainly well advised in proceeding with caution in the matter of deciding as to what is to be taught; and when this is settled a greater difficulty awaits them in deciding *how the information may best be conveyed*, on a scheme suitably graduated to the ages and the capacities of the scholars. The value of *the right sort of teaching* cannot be over-estimated. The ignorance among the poor of personal and domestic hygiene, including, of course, infantile rearing, is responsible in no small measure for their high preventable mortality, their inferior physique, their intemperance, and their poverty. The possession of citizens of good physical and moral stamina is the most valuable and abiding of all national assets, and for this the nation is very largely dependent upon what the educational influences of school life are made to be.

I am, Sirs, yours faithfully,
HENRY KENWOOD.

Public Health Department, University College, W.C.,

SHOCK AND COLLAPSE.

To the Editors of THE LANCET.

SIRS,—Mr. P. Lockhart Mummery has produced no evidence in support of his assertions that increased atmospheric pressure is of value in the treatment of shock and that this increased pressure can alter the distribution of blood in the vessels. Until he does so these assertions remain pure hypotheses, unsupported by facts and contrary to ordinary physical principles. Mr. Mummery is astonished at the way in which the vaso-motor system is able to cope with variations of external pressure. (Will he explain how it does so?) To me it seems that the vaso-motor system has nothing to do with it but that the phenomena are to be explained by purely physical principles.

The vascular system consists of a closed system of elastic tubes containing an incompressible liquid. The blood pressure is maintained by the force exerted by the heart and the resistance to the blood flow in the vessels. Alterations in the blood pressure can be produced by alterations in the force or rhythm of the heart beat (which we can leave out of account in the present discussion) or by alterations in the peripheral resistance. *Local* increase in the peripheral resistance, as by localised external pressure, will produce an alteration in the distribution of the blood by driving the blood into that part of the system which is not subjected to pressure and, in consequence, the vessels in this part of the circulation will dilate and their tension and therefore the blood pressure will be increased. On the other hand, a *general* increase in the external pressure cannot produce any alteration in the distribution of the blood because the pressure will be exerted equally at all parts of the system. It remains, therefore, to prove that the increased atmospheric pressure does reach to all parts of the vascular system. This proof follows readily on ordinary hydrostatic principles. The majority of the tissues of the body are in a semi-fluid condition and all the tissues are permeated by an incompressible fluid which fills all the tissue spaces and lymphatic channels. Through this fluid the external atmospheric pressure is transmitted as easily as through the blood and any increase of external pressure is transmitted to all parts of the vascular system with equal force and therefore cannot alter the distribution of blood in the vessels. Under these conditions the absolute pressure in the blood-vessels is raised in the same proportion as the external atmospheric pressure and the relative pressure—that is, the blood pressure in the ordinary sense—remains unaltered. I am, Sirs, yours faithfully,

CHARLES POWELL WHITE.

St. Thomas's Hospital, April 10th, 1905.

LEGISLATION FOR FEMALE CLERKS.

To the Editors of THE LANCET.

SIRS,—With reference to Dr. T. E. White's letter in THE LANCET of April 8th, p. 959, ample legislative powers already exist for dealing with such cases as Dr. White describes. In the metropolis, Section 38 of the Public Health (London) Act, 1891, requires sufficient and suitable accommodation, with proper and separate accommodation for persons of each sex, to be provided in every factory, workshop, or workplace. In the provinces similar powers to require such accommodation to be provided are given by Section 22 of the Public Health Acts Amendment Act, 1890, the category of premises being, however, slightly wider than that in the Section 38 referred to above. There is no satisfactory definition of "workplace" but the decision given in Bennett *v.* Harding (1900), 2 Q.B. 397, is wide enough to meet all requirements. There is, I venture to think, no need for further legislation, only for more activity on the part of local authorities to put into force the powers which they already possess.—I am, Sirs, yours faithfully,

REGINALD DUDFIELD, M.A., M.B., D.P.H. Cantab.

Paddington, W., April 10th, 1905.

"AMAAS."

To the Editors of THE LANCET.

SIRS,—Had Dr. George Turner taken the trouble to read with care my paper on Amaas, which appeared in THE LANCET of May 7th, 1904, he would have noticed that, far from contending amaas to be a distinct disease from small-pox, the view succinctly stated in the concluding sentence of my paper is to the effect that amaas is considered to be variola modified by some undetermined factor or factors. This view I shall consider myself justified in retaining until the experimental evidence adduced of the susceptibility of amaas patients to vaccinia is successfully refuted. In the 14 subjects of amaas vaccinated three to five weeks (not an indefinite number of years) after the outbreak of the eruption all 14 cases proved susceptible to vaccinia.

I am, Sirs, yours faithfully,

King's College, April 10th, 1905. W. E. DE KORTÉ.

THE WEST INDIES: THEIR VALUE AS A HEALTH RESORT.

To the Editors of THE LANCET.

SIRS,—The West India Islands, especially Jamaica, have lately come much to the front as a health resort for British and American tourists. I have recently returned from a five months' sojourn in the latter colony and, having had very exceptional opportunities for visiting almost every part of the island, was particularly struck by the fact that the districts of Jamaica, affording most advantages to invalids both in climate and beauty of surroundings, were almost neglected. Visitors to the island flock to the fine hotels in and near Kingston, Port Antonio, and Mandeville. The climate of the latter, reached by an easy railway journey from Kingston and a few miles' drive, is all that could be desired. To the invalids, however, the bustle and conventionality attendant on a busy season were sources of vexation and disappointment. Yet had they known it, within easy reach of them, for Jamaica is a small island, were districts of matchless beauty, of superb and equable climate, and, above all, of simple and inexpensive living.

After close observation and with experience of Egypt and the Canaries I believe that for cases of neurasthenia, chronic rheumatism, and pulmonary disease, no climate could excel that of the uplands of Jamaica. To those to whom a sea voyage is a trial the island can now be reached in ease and comfort by the Direct Line steamers in ten days or a little over. The practitioner who recommends Jamaica would do well to advise his patient not to stay too long in Kingston but to go up country at once. To my mind the beautiful stretch of mountainous country that lies between Mandeville (accessible by railway) and Brown's Town (easily approached from the sea) possesses the most perfect climate in Jamaica. Between the townships of Christiana and Ulster Springs the mountains rise to a height of 3000 feet with good roads. The days are never too hot for a fair amount of walking or riding exercise; the nights are delightfully cool and pleasant; the trellis work with which nearly every window is fitted makes it impossible for the phthisical patient to shut out the air even if he cared to do so. He can drink spring water instead of the tank water so prevalent in Jamaica and he will find the natives a most courteous and law-abiding people. Mosquitoes are rare, in the higher districts practically unknown. All kinds of delicious fruits are at his service at a merely nominal price; indeed, the orange and mango can be had for the picking. The exquisite charm of the scenery, the purity of the mountain atmosphere, the outdoor life—for he need go no further than the verandah if he does not care to stir abroad—the absence of bustle, the increased appetite, and the sound and refreshing sleep soon produce a very marked change in the patient. To the well-to-do of either sex I believe Jamaica affords unrivalled opportunities for repose of mind and body. The climate and life are ideal for convalescents and in phthisis, in the many cases which I have been able to authenticate, the results were remarkably good. In the latter the beneficent results were especially marked in those who had abandoned the tourist track in favour of the unconventional life of the *real Jamaica* in the uplands. The boarding houses, and there are far too few of them, are clean, comfortable, well-served, and not expensive. But why is there no sanatorium in that beautiful and health-giving district?

The conscientious practitioner, who remembers the humble circumstances of his patient before ordering him abroad, will do well to think of Jamaica. For females who have to earn a living there are, unfortunately, few opportunities there. But for the male, whatever his previous training may have been, who is willing to spend a few months in learning the rudiments of agriculture or stock-raising, the island offers a good living. A pleasant life it is, too, compared with the rough and tumble of South Africa. He will not be long a "stranger" there. The Jamaicans are models of kindness and hospitality.

I am, Sirs, yours faithfully,

April 10th, 1905. A. A. BARCLAY, M.B. Glasg.

THE TREATMENT OF EMPYEMA.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of April 1st Mr. Rickman J. Godlee quite rightly makes a protest against the surgical treatment of empyema, as laid down by Dr. S. West in your issue of March 25th, but he has not called attention to these statements in Dr. West's paper: "It sometimes happens that a case of empyema comes under observation in such a condition that immediate operation seems risky and then paracentesis will give relief and gain time till the patient is in a better state to stand the incision. ...... Of course, if paracentesis be performed for empyema the aspirator must be employed."

I presume that the "risk" referred to is the danger of the anæsthetic on account of the presence of a large amount of fluid within the chest mechanically impeding respiration and the heart's action; as well as the weakness of the cardiac muscle from the general toxæmic condition of the patient. In cases such as these I have not found paracentesis by means of an aspirator satisfactory. No doubt the removal of the pus will for a short time relieve the mechanical pressure, but it will not prevent further absorption of toxic products, and I have also found that very soon there occurs a fresh throwing-out of fluid from the walls of the empyema and thus the mechanical pressure is reproduced. The treatment for these "risky" cases is, in my opinion, to put in a trocar and cannula, with strict antiseptic precautions and under local anæsthesia, and to leave the cannula in to drain off the pus quietly and slowly.[1] This not only relieves the mechanical pressure but also arrests the absorption of toxic products. After from four to ten days, the cannula not having been removed, according to the severity of the case the improvement in the patient's condition will allow an anæsthetic to be administered with impunity. Part of a rib may then be excised, the lymph removed, and the cavity thoroughly explored and drained in the manner recommended by Mr. Godlee.

I am, Sirs, yours faithfully,

Queen Anne-street, W., April 3rd, 1905. WILLIAM TURNER.

THE EPIDEMIC OF PLAGUE IN INDIA.

To the Editors of THE LANCET.

SIRS,—I have read your leading article "Plague in India" with interest and appreciation and having had some years' experience on plague duty share in your misgivings. The Indian Plague Commission advanced our knowledge but little and in my opinion this was owing to the fact that a great part of its time was expended in hearing the evidence of witnesses. This naturally involved much repetition; written reports would have saved time and probably have been clearer. The time of the scientific members would have been more usefully devoted to *personal* bacteriological and experimental research.

It is essential that the India Office should thoroughly appreciate the importance of the inquiry being conducted on the spot by the most able bacteriologists procurable and that [illegible]. The inquiry should aim at affording [illegible] following: 1. The life-history of [illegible] [illegible]ow does the human body become infected? 3. How and where does the bacillus pestis exist during the intervals between epidemics? 4. How is it that the most careful and thorough disinfection fails in some instances to prevent the recurrence (after an uncertain interval) of the disease on the same premises? 5. The relationship between epidemics of plague in rats and in human beings. It is a matter of general knowledge that human cases may follow on the death of rats from plague, but how the two are connected is not certainly known. 6. The manufacture and action of Haffkine's prophylactic and Yersin's serum. The prophylactic, according to my experience undoubtedly efficacious, should be standardised in order that the desired protection can be obtained without excessive inconvenience to the subject. Yersin's serum, so successful in the laboratory, has in the hospitals of South Africa given most unsatisfactory results.

I am, Sirs, yours faithfully,

Hatch End, March 29th, 1905. W. D. BETENSON.

THE AGE INCIDENCE OF CANCER.

To the Editors of THE LANCET.

SIRS,—Dr. E. F. Bashford, in his timely and very interesting address, published in THE LANCET of April 1st, p. 837, insists that "all hypotheses in explanation of the origin and nature of cancer break down, not only in not explaining how growth is maintained but also before the problem of the peculiar age incidence of the disease." The following theory will, I believe, explain the two difficulties mentioned, as well as many other salient features in the history of malignant and other new growths.

We start from Virchow's famous dictum, "Omnis cellula a cellulâ," every cancer consisting of a mass of cells starts from a previous cell, and is really only the result of a deviation from the normal mode of growth. It will be well therefore to bring back to mind very briefly the essential phenomena attending the division of a cell—whether animal or vegetable—and the normal growth of the resulting daughter cells. Consider then a cell just about to divide. When the energy or forces in the nucleus reach a certain point the nucleus divides into two parts which separate, but are joined by fine strands of nuclear protoplasm. Near the middle of these strands is deposited the new cell wall elaborated by the nuclei from the materials contained in the lymph or sap as the case may be. It is evident that the nuclei spend a given amount of energy in the construction of this new cell wall. The two daughter cells in their turn may grow and divide, the nuclei always spending a normal amount of energy in constructing the new cell wall. Such very briefly are the essential features of normal growth. There has been no mention of early and minute changes in [illegible] er only the [illegible] deviation from the above normal process which might lead to continuous abnormal growth. Assume then that we have a cell with a normal nucleus just about to divide, but assume also that some of the materials supplied for the elaboration of the new cell wall about to be formed are wanting in quality or quantity. The nuclei divide but spend less energy than is normally the case in constructing what may now be designated a poor quality cell wall. The (daughter) nuclei are thus left *overcharged with energy*. These overcharged nuclei will, it is safe to assume, divide much more quickly, i.e., after a much shorter interval of time than would be the case with normal nuclei. When they divide their daughter nuclei in turn form poor quality cell walls and so the swift and apparently unlimited growth must continue.

Such is the theory I am bringing forward to attempt to explain the incidents in the life-history of new growths and to be very brief I will mention only a few of the more salient incidents. The two difficulties mentioned by Dr. Bashford are age incidence and limitless growth. Taking the latter difficulty first the theory shows that the only limit to the growth of the cells is the complete withdrawal of nourishment—i.e., the death of the host—or the reappearance of the normal materials for elaborating a normal cell wall. This is excessively unlikely to happen, as once the growth has started the drain on the host is established, making it almost impossible for the latter ever again to supply normal nourishment. As to age incidence, we may put the matter in another way and ask, at what time in the life of an organism is the nourishment supplied to the parts likely to show deterioration? We must remember, at the same time, that the deterioration must be slight, otherwise the nuclei would suffer and there would be no growth at all. The answer to the question is, evidently just past the prime of life. For up to this time the materials supplied for growth will in general be normal. Further, cancer should be unlikely to occur long after the prime of life, for then the nuclei also are on the wane. This theory then suggests that cancer should start just after the prime of life in any animal and, further, that cancer should be less liable to start in the *very* old. Such organs as the mamma and uterus in the parous may be said to pass their prime immediately they begin their first involution, and on this theory cancer ought to occur earlier in such organs than in other parts of the body.

Any interference with the lymph or blood-supply to a part in so far as it altered the nourishment for the elaboration of new cell walls might thus start a cancer in the part. Trauma may cause such interference. Again, the cell wall being, on the theory, of lower quality than normal, a cancer ought to degenerate quickly and show degeneration products peculiar to itself. And again, this cell with its low quality cell wall and nucleus overcharged with energy—in other words, a cancer cell—is a menace to the host as long as nourishment can reach it. The change in the character of the cell wall and the quick rate of growth may account either separately or jointly for the frequent detachment of cells from one another. If such a cell be carried to another part of the body it is supplied with the same nourishment and the chances are greatly in favour of its growth in its new position—i.e., the establishment of secondary growths. In an individual of the same species, provided the cell is transplanted at a corresponding period in life, the cell ought to grow into a cancer in many cases, while if transplanted into the system of individuals of different species it ought to die, unless, indeed, the lymphs of the two hosts were chemically identical.

Finally, as a cancer cell is one with nucleus overcharged with energy it is impossible to fail to see that it is in a similar state to the cell which results from the union of the male element with the ovum and we will not be surprised to notice that in many respects cells in a cancer show resemblance to the fertilised ovum. This latter cell has a nucleus representing the combined energy of the male and female nuclei. The great point of resemblance between the fertilised ovum and a cancer cell is, of course, their characteristic tendency to divide—i.e., to growth.

Enough has been written to show that many important clinical features of new growth can be deduced from a simple consideration of the play and balance of energy in a cell. The theory, tentative, like most theories of cancer, may be found interesting if only because it shows how many points in the course of a cancer can be explained without recourse to a specific cause. I have refrained from confining the theory to malignant new growth alone, for it is evident that other tumours would come within its scope, from the most malignant to those of very slow growth. The only index to the rate of growth is the difference between the normal and new cell wall in composition. The greater this difference the swifter is the growth or the greater the malignancy.

---

[1] See THE LANCET, April 12th, 19 2, p. 1044.

I am, Sirs, yours faithfully,
R. E. ROBERTS, M.B., B.Sc. Lond.
Crosskeys, Monmouthshire, April 3rd, 1905.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of April 1st Dr. E. F. Bashford, in a very interesting paper on the Growth of Cancer, lays a good deal of stress on the unsolved problem of the age incidence of the disease. For some time it has seemed to me that a factor in the production of new growths has been a rise in blood pressure. One could give several instances where tumour formation, both benignant and malign, has been preceded by high arterial tension.

Two cases will suffice to make clear my meaning. A woman, now aged 41 years, has been under my care for the last nine years. During that period I have seen her frequently for headaches of an intense nature, due apparently to high arterial tension. Drugs seem useless but leeches to the temple give some relief. She has also had to wear a pessary for prolapse of the uterus following her last confinement 11 years ago. The patient has seen several physicians and gynæcologists but without relief to the headaches. 18 months ago she developed a fibroid of the uterus which now reaches within an inch of the umbilicus. It is worth noting that before the tumour appeared the heart showed signs of dilatation. Recently the blood pressure by Hill and Barnard's sphygmometer registered 180 millimetres of mercury but such records are of small value unless its relation to the force of the heart-beat is considered. For example, with a very feeble heart-beat the tension might be relatively high, while the sphygmometer might register it as apparently low.

The other case was in a man, aged 72 years. Eight years ago when I saw him for a minor ailment one noticed that his blood pressure was very high and the arterial tone increased. A year later he came with a cancer of the lip, the exciting cause being a clay pipe. The growth was examined microscopically after removal and was certainly malignant. There has been no recurrence, though the blood pressure is still high, and the only change in habits is that the man has given up smoking.

In both these cases there were high arterial tension and also irritation, the one from changes in the uterus following the prolapse and the other from the clay pipe. Since blood pressure presumably tends to rise in all vertebrates in later life it may account for the age incidence in cancer. It is to the general practitioner that one must look to confirm or to refute this view, for, like myself, he has the opportunity to follow cases over long periods of time. As to why increased blood pressure might cause aberrant growth must be somewhat speculative; but if, as some maintain, high arterial tension is due to changes in the density of the blood plasma this would cause a change in osmotic pressure. A change in the normal osmotic pressure as a factor in the production of aberrant growth can be well seen in the eggs of the frog or sea urchin. I am, Sirs, yours faithfully,

Formby, April 3rd, 1905. ARTHUR C. WILSON.

THE TREATMENT OF HÆMORRHOIDS BY THE HIGH-FREQUENCY CURRENT.

To the Editors of THE LANCET.

SIRS,—As we have recently heard a great deal of the value of high-frequency treatment for internal piles I thought it might prove of value to record the following case.

On Dec. 24th, 1904, I was consulted by a gentleman, aged 51 years, suffering from internal hæmorrhoids, which were then inflamed and prolapsed. On Jan. 4th, 1905, the inflammatory condition having subsided, he was, at my request, examined by a surgeon on the staff of one of our special hospitals for rectal diseases so that the exact condition of the parts might be ascertained before high-frequency treatment was commenced, which I was desirous he should try, as the case, to my mind, was a typical one for testing the value of this method and the patient was naturally anxious to avoid an operation. On Jan. 5th high-frequency treatment was commenced by a surgeon on the staff of the electrical department of one of our London hospitals, with the understanding that he might continue the treatment as long as he thought necessary and applied by whatever method he thought fit. On March 29th, the patient having had 32 applications, the surgeon said he could do no further good, even if he had done him any good at all. On March 31st he was again examined by the surgeon on the staff of the special hospital who had seen him on Jan. 4th. The surgeon informed us that the condition was practically the same as on that occasion and that an operation was as necessary now as it was before the high-frequency treatment had been commenced.—I am, Sirs, yours faithfully,

Wimpole street, W., April 3rd, 1905. GEO. STEELE-PERKINS.

ABOUT AUTOGENOUS INSTITUTES.

To the Editors of THE LANCET.

SIRS,—I have noticed in the advertising columns of the medical journals lately statements of analysis issued from sources bearing the titles of "Institute of Hygiene," "Institute of Bacteriology," &c. I humbly submit that it is necessary at once sternly to reprobate this practice—namely, that a fortuitous congeries of individuals should elect to call themselves an "Institute" of Bacteriology or the like and issue certificates of commendation to impress the public or the profession. So far as regards the "Institute of Hygiene" I believe that the gentlemen composing it are of the highest probity and of the greatest eminence. Some of them I know, personally and by repute, and I have the greatest respect for their attainments. But it is obvious that those very excellences which may guard this particular "institute" from adverse criticism will be availed of by less scrupulous folk to foist other "institutes" into being. If we are to tolerate these what is to prevent any half dozen chemists from joining with a couple of medical men and announcing themselves as an "Institute of Pharmacology," which will be prepared to examine and to report (for a fee) on any pharmaceutical preparation? Or a few needy medical men combining with an architect or two and constituting an "Institute of House Hygiene," prepared to bless or to blame every article used in the house? The possibilities of prospective fraud are too awful to contemplate.

I am, Sirs, yours faithfully,
J. C. MCWALTER, M.D. Brux., M.A., D.P.H.
April 9th, 1905.

DANGERS TO THE OPERATOR FROM THE X RAYS.

To the Editors of THE LANCET.

SIRS,—An annotation in THE LANCET of April 8th, p. 945, on the above subject begins: "Though the injuries inflicted on the patient in the use of the x rays have been repeatedly recorded little attention has been directed to the dangers to the operator." Such a statement is, in my opinion, rather too sweeping, as many hospitals and also private workers take precautions to protect the operator from the influence of extraneous rays. At the London Hospital shields made of thick glass containing a high percentage of lead are used. The rays are allowed to fall only where they are wanted and the rule is to take radiographs in all cases, the screen being used only where the peculiar circumstances of the case render it necessary. Under the arrangements there it is considered to be practically impossible for the operator to become seriously damaged and if it does happen it will be due to his own carelessness in not availing himself of the means provided for his safety. That operators in the London Hospital have suffered severe injury in the past is only too true, but nothing fresh has happened since the introduction of the x ray shields over 12 months ago. This is a matter for congratulation considering that we have six sets of apparatus in constant use.

I am, Sirs, yours faithfully,
REGINALD MORTON,
Medical Officer in Charge of the Electrical Department,
London Hospital.
April 11th, 1905.

CHOLERA, PLAGUE, AND OTHER DISEASES IN THE NEAR EAST.

(FROM THE BRITISH DELEGATE TO THE OTTOMAN BOARD OF HEALTH.)

SINCE the date of my last letter, which appeared in THE LANCET of March 4th, p. 604, no case of cholera has been reported from any part of the Turkish Empire. It is hoped, therefore, that the epidemic is now extinguished. Reports are still coming in with details of the outbreaks in various places, outbreaks which have already been mentioned in my earlier letters and which fortunately have now little more than an academic interest. During the epidemic in the town of Van there appears to have been a considerable mortality among the troops stationed there and a smaller mortality among the general population. Several villages in the neighbourhood were also invaded by the disease. A large number of villages in the neighbourhood of Deir-Zor, on the Euphrates, in the Aleppo vilayet, were also the scenes of outbreaks of more or less severity, but here also the epidemic seems to be over. In December it was rumoured that the disease was prevalent among the nomad Arabs who winter their flocks in the province of Deir-Zor. The presence of cholera at Bitlis has never been reported, but from information recently received it appears that there was an extraordinarily high mortality there among recruits in the latter months of last year and among the Armenian population (and, it is added, presumably among the Kurds also) the mortality rose to double the average. A still higher mortality is said to have prevailed at Mush but up to the present no definite information is to hand to show that either here or at Bitlis the raised mortality was due to cholera.

The outbreak in Persia has also greatly diminished but it is doubtful whether it has yet completely disappeared. The following is a summary of the latest reports received by the Board of Health here from its representative in Tehran, which bring the history of the epidemic down to March 7th. The Customs authorities had reported on Jan. 18th that no case of cholera had occurred in Shuster or Dizful for the preceding 15 days but at Kermanshah during the first week of that month there had been an unusual mortality from a disease accompanied with diarrhœa and vomiting, particularly among children. Cases of cholera were still occurring at Kasr-i Shirin, near the Turkish frontier, but the disease had apparently disappeared from the Mazanderan province and no case had been seen at Meshed-i-sar since Dec. 15th. Cases had recently been observed at Kumesheh and Abadeh on the road between Ispahan and Shiraz.

Another report dated Feb 1st stated [illegible] the information given in an [illegible] last letter) that the weather [illegible] of exceptional severity. Snow had fallen to a depth of from two to three metres and the thermometer had sunk as low as –17° Réaumur (6¼° below zero, Fahrenheit). This is said to be the lowest temperature recorded for 30 years. Cholera had at this date recently made its appearance at Birdjend where it was causing from 15 to 21 deaths daily. A third report, dated Feb. 8th, quoted from information received in December last from the south of Persia, according to which all that part of the country and the shores of the Persian Gulf were at that time in a satisfactory state in respect of epidemic disease. Cholera had disappeared from Mohamera in the first half of December, but in the last week of that month it had broken out at Jask, against which port a quarantine of four days, including the voyage, had been imposed by the local sanitary authorities. Reports from Tabriz, dated Jan. 15th, stated that cholera had completely disappeared from there. The Customs authorities of Kermanshah announced on Feb. 1st that cholera had apparently become endemic in Kasr-i-Shirin and its neighbourhood, especially among the Djafs, Mahmudis, and other Turkish tribes wintering there. On Feb. 6th it was reported from Khaf that the total mortality from cholera in that town and the surrounding villages had been not less than 700 persons. Cholera had disappeared from among the mining population at Nishapur where the disease broke out in the first week in January and where as many as 150 deaths had occurred. On March 1st it was stated that a few cases were still occurring at Kum and Birdjend; and finally, on March 7th the Turkish sanitary representative at Kermanshah reported that all northern and western provinces of Persia, as also the towns of Kazvin, Hamadan, and Tehran, were free from cholera; that the disease was still present at Kum; and that information was lacking as to its existence or behaviour in the southern provinces.

The reports quoted above make mention of the presence of other diseases in many parts of Persia. At Senneh (? Sehna) small-pox was seriously prevalent in January; it had caused there over 200 deaths in a short period and it was spreading to other parts of Kurdistan. The same disease was also epidemic at Nehavend, Burujird, and Tehran. In February it was also active at Tabriz, Kengaver, and Senneh. It is noteworthy that small-pox inoculation is still practised in these Persian towns, but no precautions are taken as to [illegible] icking the skin of the unfortunate [illegible] to the process; and the result is [illegible] those inoculated die either from the disease itself or from blood poisoning. Typhus fever is mentioned in several of these reports, but it is not clear whether petechial typhus fever or enteric fever is to be understoood by this term. It has been reported from Kengaver, Nehavend, Burujird, Tabriz, and Senneh. Enteric fever and other intestinal disorders were very prevalent in Tehran in January. Diphtheria was present in Kengaver and Tabriz in the same month.

In Russian territory the cholera epidemic has almost completely died out. Between Jan. 16th and 23rd[1] only six cases and four deaths were reported from all parts of the country (one fatal case at the Alexandropol railway station, in the Erivan government, and five cases with three deaths at Tsaritsyn); between Jan. 31st and Feb. 10th only two cases of the disease were reported, one at Baku and one in the Uralsk province, between Feb. 17th and 24th only a single case occurred—at Balakhani, near Baku; and finally between Feb. 25th and March 4th no case of the disease was reported from any part of the Russian Empire.

The outbreak of pneumonic plague among the Kirghiz and Cossack population in the Uralsk province came to an end on Jan. 8th in the Bukeëf Horde and on Jan. 16th in the Gurief district of the province. The serious outbreak of anthrax ("Siberian ulcer") in the Viatka government, reported in my last letter, has to a great extent subsided. In the week ending Jan. 24th t[illegible] was 11; between Jan. 31[illegible] (bringing the total from [illegible] 10th to the 17th, 32 cases; from the 17th to the 24th, 19 cases and four deaths; and from Feb. 25th to March 3rd only six cases.

Some interesting details of this outbreak have recently been made known in a paper communicated to the Saratof Physico-Medical Society by Dr. Vigura and Dr. Konstansof. The outbreak began about Dec. 7th and by Jan. 6th it had caused 420 deaths. Not a single case recovered. The first case occurred in a Kirghiz settlement, close to the northern shores of the Caspian Sea. Nothing can be ascertained as to the source of infection, if for no other reason because the whole of the population of the infected settlement have died from the disease. The funeral ceremonies ("*pominki*" or wake) were attended by Kirghiz and Cossacks who spread the infecti[illegible] miles) was soon infected. A description is given of the precautions taken by the medical and other members of the staff who were sent to deal with the outbreak, and it is stated that while only two "feldschers" and none of the soldiers who followed these precautions contracted the disease, all the voluntary assistants (who did not take the precautions) caught the disease and died.

A severe epidemic of typhus exanthematicus has been recently prevailing in the town of Vladimir. It began in December last and assumed serious proportions in January. Between Dec. 18th and Jan. 24th as many as 115 cases of the disease had been recorded. Between Jan. 30th and Feb. 10th there were 30 fresh cases; for the next week the figures are lacking; finally, between Feb. 18th and 24th 14 cases were reported.

The outbreak of plague at Aden, mentioned in my last letter but one,[2] reached its highest point in the week ending

Constantinople, April 3rd.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Crossley Sanatorium.

AT the annual meeting of the friends and supporters of the Manchester Hospital for Consumption which was held at the town hall on March 31st Mr. Crossley stated that at the moment of the meeting the first 12 patients were on their way to the sanatorium in Delamere Forest. The formal opening will take place in July and it is hoped that the King will perform the ceremony. The sanatorium contains 95 beds and has been built at a cost of £80,000, if not more, and is now handed over, fully furnished and ready for use, to the Hospital for Consumption. It is a munificent gift on the part of Mr. Crossley who sets an example of philanthropic liberality that others of our rich men might follow. It is calculated that a yearly income of £6000 will be required. There is an endowment fund which now amounts to about £57,000 and provides an income of £1800. In his speech at the annual meeting Mr. Crossley said that a further sum of £4200 is required annually "in order that the increased accommodation provided may be fully utilised by the many poor patients in Manchester and the neighbourhood who are now waiting for admission." He made a strong appeal to "people of means" to help in the work. It would be deplorable if the splendid accommodation at the sanatorium and at the hospital at Bowdon could not be fully used for lack of annual income.

Infectious Disease and Elementary Schools.

In his annual report Mr. F. McDougall, the medical officer of health of Runcorn, says that during last year there were 303 cases of infectious disease notified, an increase of 118 cases over the previous year. He drew attention to the part played by schools in spreading scarlet fever, of which there were 153 cases. Some children went to school in an infected condition and possibly also some mild cases were not notified. He says that "the attempt to drive back to school children who had been away sick should be done with extreme caution" and that the education authority should require a clean bill of health before a child is readmitted to school. Financial reasons, in addition to zeal for education, are likely to lead to a too early return. The medical officer of Dukinfield thinks that the scarlet fever was not conveyed there by water or milk but that the scarlet fever germ lives and thrives in the district and is readily conveyed by infection.

Small-pox.

Here in the north small pox is far too prevalent and in view of what is known of its causation and prevention it is allowable to say disgracefully prevalent. A somewhat serious outbreak is reported from Bradford. It is stated that about a fortnight ago a wool-sorter died after eating fish and chipped potatoes. There was an inquest and the verdict was "Death from ptomaine poisoning." On the face of it this does not seem to have any necessary connexion with small-pox. But from the house he occupied and from the next thoroughfare eight cases of the disease were removed. It is also reported that the person who laid out the man's body after the post-mortem examination for the inquest has died suddenly. The medical officer will make a full report to the health committee as is certainly desirable. To-day's report is that three fresh cases have been notified at Bradford. In Oldham last month there was a prosecution that failed apparently because the letter of the law is of more importance than the protection of the people from small-pox. A collier was summoned for not notifying cases of small-pox, he and his wife and a son suffering from it. The defence was that he had no idea it was small-pox. The presiding magistrate said that he did not believe him but the magistrate's clerk struck in with the information that "there are doctors who cannot tell small-pox," and warned the magistrates (very kindly) that they must not convict a man unless he is proved to be guilty, saying "you have no evidence of knowledge at all," and that on the evidence they could not convict. The bench were unanimous in their opinion that the man knew that he was concealing small-pox and were exceedingly sorry that they were not able to mark their sense of the danger to the community of that sort of thing upon a man whom they believed to be guilty. It would no doubt be wrong to attribute to the clerk any wish to aid in the spread of small-pox, but so acute a person would by a few well-directed questions have been able to test the truth or falsity of the plea of ignorance. Burnley has suffered rather severely and is not yet free from the disease, and it is stated that at this date there are eight cases in the Newcastle Town Moor Hospital. Nor is Halifax free from the disease, six cases being now in hospital, while towards the end of March a death from the disease took place at the Ainsworth Small-pox Hospital, the patient, who had not been vaccinated since infancy, having come from Bury. About the same time the mayor of Stalybridge and Mr. F. J. Roberts-Dudley were asked to grant a certificate of exemption from vaccination, but the latter declined, so other magistrates were waited for, one of whom agreed with the mayor to sign the certificate. The former regretted that he and Mr. Roberts-Dudley did not agree on the matter and received an answer that should help those who are so ready to give exemption certificates to understand the responsibility which they incur. "I could not sign such a certificate. If I did and that child caught the small-pox and died I *should* consider that I had signed its death warrant." At Accrington, too, there has been a serious epidemic which has created somewhat of a scare. Last week 16, if not more, cases were taken to hospital, among them an antivaccinationist and his four children—all unvaccinated. Several more cases have been reported from Heywood. At Preston a case occurred a short time since which is instructive as showing what some people will do to conceal the fact that they have small-pox. An inspector found that a woman was suffering from the complaint. She admitted that she had been ill five weeks and had hidden when an inspector had previously called. In consequence of her conduct ten persons were attacked. This distributor of the disease was fined 1*s.* and costs—a penalty that will no doubt strike terror in such offenders. This is an unsatisfactory state of things. One would like to see it dealt with by a practical people, which we cannot claim to be, like the Japanese.

The Mersey and Irwell Committee.

At the last meeting of the Mersey and Irwell joint committee there was some discussion as to the appointment of chemical adviser, which position has been held by Sir Henry Roscoe since the formation of the committee 15 years ago. The question had been referred to the chemical subcommittee which reported that without considerably increased expenditure the services of a chemical adviser, whose position and opinion as a man of science would have weight with local authorities, could not be obtained if he were entirely excluded from private practice. But as the joint committee desired that there should be closer touch between the chemical adviser and the committee and its work, it was recommended that Mr. Scudder, chief chemical assistant, should be appointed in succession to Sir Henry Roscoe at a salary of £725 per annum, inclusive of travelling expenses, &c., on condition that "neither he nor any partner of his shall advise or act in connexion with any matter relating to sewage or trade effluents within the Mersey and Irwell or Ribble watersheds." It was felt by many of the committee that Sir Henry Roscoe was not being treated "with the consideration due to his long and able service," and in the end it was decided to ask him to retain the office for another year. The results of the examination of 36 samples of sewage effluents from the works of local authorities showed 19 good, 13 fair, two unsatisfactory, and two bad. This is one of the best results received and, as a member said, showed that something was being done to improve the rivers under their control. The supply of water for trade and domestic purposes is so difficult a matter that in view of the apparently diminishing rainfall all sources of supply should be considered. At Cleckheaton the public baths are supplied by water pumped up from the old coal-workings and after filtration it is said to be "of a beautiful transparency and blue rather than yellow in tone." The cost is about 9*s.* per 50,000 gallons. It is possible, too, that trade effluents may be more utilised than at present. Mr. A. M. Fowler, C.E., of Manchester, says that about [illegible] the Ship [illegible] t Fowler, [illegible] now quite up to the standard of the Irwell and Mersey rivers committee. Now, he said, "if that was so, that effluent water was practically as pure as some of the Thames water supplies and some drinking supplies in various parts of the country." It is doubtful if this statement will rouse the enthusiasm of the water drinkers of London, however gratifying it may be to members of the Mersey and Irwell committee.

April 11th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Meeting of the Royal Sanitary Institute at Bristol.

THERE will be no general congress in connexion with the Royal Sanitary Institute this year. A conference upon school hygiene, together with a small exhibition, was held in London in February and the council of the institute has arranged a series of provincial meetings during the year. One such meeting has already been held at Nottingham and others are to be held in Liverpool and Birmingham. The city of Bristol was chosen for a meeting on April 8th when the subject of isolation hospitals was considered. In opening the discussion Dr. D. S. Davies, medical officer of health of the city, dealt first of all with the necessity for isolation hospitals and said that it was an axiom that the temporary seclusion of a person suffering from a communicable fever which came to an end in a short period should succeed in preventing any definite spread of the disease in question provided the following essential conditions were fulfilled—namely, (1) that the patient had not handed on his infection to any other person before his seclusion commenced; (2) that the patient had left behind no infected material, or if he had that it had been rendered sterile; (3) that the patient was kept perfectly secluded through the whole of his illness and convalescence from direct or indirect communication of his disease to others; and (4) that the patient had perfectly recovered before he [illegible] in any [illegible] entive [illegible] isola- [illegible] iseases which were specially isolated in Bristol, these being small-pox, typhoid fever, scarlet fever, and diphtheria, and he emphasised the importance in the case of the two last of seeking for "missed" cases. He proposed the following motions which were seconded by Dr. J. Howard-Jones and carried unanimously:—

> That the provision of hospital isolation accommodation for large centres of population is imperative, and that one bed per 1000 of the population is a good working minimum.
>
> That the opposition to such provision is based on a lack of appreciation of the essential conditions that contribute to the success of isolation.

Mr. T. H. Yabbicom, the city engineer, gave an interesting account of the Bristol isolation hospitals, from which it appears that there was a small-pox hospital with 53 beds in temporary wooden buildings and eight beds in permanent wards and a permanent hospital situated about four miles from the city for the isolation of diseases other than small pox. This hospital, which is built of brick, can accommodate 135 patients. The pavilions are built on the Local Government Board plan and include four one-storey buildings and one of two storeys. There are also four observation wards. The total number of beds, including those in the temporary buildings, available for the isolation of infectious diseases in Bristol is thus 196. The population of the city is 358,000; it is not surprising, therefore, that various speakers should have pointed out how inadequate this number was to meet the needs of a city such as Bristol. Mr. Herbert Jones, Dr. J. Middleton Martin, and Mr. J. Tubb-Thomas emphasised the importance of reducing the cost of building if sanitary authorities are to erect hospitals more generally.

A County Medical Officer of Health for Somerset.

In spite of considerable opposition, as mentioned in THE LANCET of March 18th, p. 751, the Somerset county council decided on April 4th to appoint a medical officer of health. The terms of the appointment are that he shall not devote the whole of his time to the duties of the office and shall be paid a salary of £150 annually with a fee of five guineas daily when engaged upon making special investigations on behalf of the council, such fees not to exceed £100 in any one year. It is probable that at the end of this year the administration of the Midwives Act will be placed in the hands of the medical officer of health.

Shabby Treatment of a Medical Officer of Health.

The necessity for giving security of tenure to medical officers of health has been once more illustrated in the treatment which has been experienced by Dr. Francis T. Bond at the hands of the Chipping Sodbury rural district council. Dr. Bond has been medical officer of health of the district for 32 years at an annual salary of £115. In October, 1904, the Barton Regis district was broken up, most of it being added to the city of Bristol and three parishes with a population of 4600 being added to the Chipping Sodbury rural district. The medical officer of health of Barton Regis having recently died the Chipping Sodbury council asked Dr. Bond to undertake the supervision of the added parishes but without any extra remuneration. This Dr. Bond very properly refused to do and after an appeal to the Local Government Board he was given an increased salary of £33 per annum. His term of office will expire in May and instead of reappointing him the council has advertised for an officer at a salary of £120 yearly. The Local Government Board has mildly protested and in doing so has pointed out that the fact of Dr. Bond residing away from the district is no dis- [illegible] that it is a distinct advantage to be able to [illegible] It [illegible] il is [illegible] This, however, is not so but rather the reverse.

West Wales Sanatorium.

The foundation stone of the West Wales Sanatorium at Alltymynydd (two and a half miles from Llanybyther station) will be laid on April 26th by H.R.H. Princess Christian of Schleswig-Holstein, accompanied by her daughter the Princess Victoria. The band of the Carmarthenshire Militia [illegible] concert of Welsh national music [illegible] the Lord [illegible] Tickets [illegible] number of platform tickets at one guinea may be obtained from the Secretary, Sanatorium Concert, Llanybyther, Carmarthenshire.

Archæology in Somerset.

At the meeting of the Somerset Archæological Society held at Taunton Castle on April 6th a valuable collection of archæological, ethnographical, and geological specimens was presented to the Taunton Museum by Mr. Hugh Norris, L.R.C.P., L.R.C.S. Edin., of South Petherton. The curator of the museum (Mr. St. George Gray) gave an interesting account of the collection and alluded to the extreme rarities which it contains. After the gift had been suitably acknowledged by the President, a hearty vote of thanks was awarded to Mr Norris. This was replied to by his nephew, Dr. R. H. Walter, as owing to his failing health Mr. Norris could not be present. Subsequently Professor Lloyd Morgan, principal of University College, Bristol, delivered an address on the educational value of museums.

Ebbw Vale Colliery Surgeons.

For many years the relations between the colliery surgeons and the employés of the Ebbw Vale Steel, Iron, and Coal Co. were all that could be desired, but the introduction a few years ago of an entirely different system to that which formerly prevailed has made the conditions of practice not only onerous to the surgeon but unsatisfactory to the workmen and to their families. As long ago as 1880 Mr. J. W. Davies was appointed by the doctor's fund committee of the works as the workmen's surgeon. He was paid on the poundage system, 2*d.* in the pound being deducted from the men's wages at the company's offices on behalf of the committee and paid over to him periodically. He paid all the expenses of the practice, including the payment of such assistants as were necessary. Some years later an arrangement was made so that the workmen in this and the adjoining districts could be attended by any surgeon irrespectively of the locality in which he lived and the stoppages out of the men's wages were credited accordingly. In 1903 five divisions were formed, to each of which a chief surgeon was appointed (Mr. Davies being one) at a salary of £500 annually, the committee paying the salaries of assistants, the surgery expenses, and the cost of all drugs. The assistants were appointed and controlled by the committee but the chief surgeon was responsible for the carrying on of the work. The chief surgeons were not debarred from private practice or from holding public appointments but each was restricted to practise in his own district, with the result that the managers and chief works' officials protested that they had no choice as to who should be their private medical attendants and they accordingly appointed a surgeon of their own at a salary of £500 per annum, with permission to undertake unrestricted private practice. At the end of 1904 a still further restriction was sought to be imposed by the workmen's committee and the chief surgeons received notice to give up all private practice, the object apparently being to compel the tradespeople and other residents not employed in the works to subscribe to the doctor's fund. Mr. Davies then resigned his position as colliery surgeon but continued in private practice and to hold his public appointments of medical officer of health of the Ebbw Vale urban district and Poor-law medical officer and public vaccinator. At the end of last month a further notice was given by the committee to the chief surgeons to give up all private practice and all public appointments, or in the alternative to consent to a reduction in their salaries equal to the amount earned in this way. Owing to the death of Dr. A. Keith Campbell the committee is now seeking the services of a chief surgeon to take his place and it behoves all those who apply for the position to make quite sure of the conditions under which it is proposed to make the appointment. The Monmouthshire division of the British Medical Association is actively concerning itself with the dispute.

SCOTLAND.

(From our own Correspondents.)

Sanitation in the Nineteenth Century.

At a meeting of the Royal Philosophical Society of Glasgow held recently Dr. A. K. Chalmers, medical officer of health, delivered a lecture on the Development of Sanitation during the Nineteenth Century. During this period, he said, disease had come to be regarded not only as a misfortune to the individual but also as a factor in the national welfare. Although we had added considerably to our knowledge of the causes of disease, we had probably gained more by calling into operation forces that were social and political rather than medical. Dr. Chalmers thought that advance might be made in the direction of devising some method of supervision which would bring the many functions of local administration into coördinated action. To illustrate this he drew attention to the fact that within the municipal area of Glasgow there are for sanitary purposes 25 subdistricts corresponding to the whole of Glasgow school board area and portions of five others (Govan, Springburn, Maryhill, Cathcart, and Eastwood), and to no fewer than five Poor-law parishes (Glasgow, Govan, Eastwood, Cathcart, and Rutherglen), none of which was wholly included; also police divisions and registration districts were not comparable with one another or with any of the divisions mentioned above. Should some method be devised of coördinating those different forms of local administration they might gain a considerable amount of useful knowledge as regards the relation of pauperism to insanity, of neglected school children to both, of crime to both poverty and insanitation, and of insanity to the prevalence of particular diseases. In addition this method of coöperation might enable the various departments to arrange the expenditure in such a way as to be distributed more equally over several years and on that account it would appeal to the ratepayer.

The Marine Biological Association of the West of Scotland.

Dr. James F. Gemmill presided at the annual meeting of the Marine Biological Association of the West of Scotland which has its station at Millport. The report records another year of very successful work and the completion of the large extension of the station, thanks to the generosity of Mr. James Coats, jun. From the corporation of Glasgow for two years a grant of £100 had been received and this has enabled the association to establish a reserve account and also to carry forward to next year a balance of £8 12*s.* 6*d.* The visitors to the Robertson museum for the year numbered 6946 and the teachers' classes were well attended. The programme for 1905 includes a connected course of three or four years' progressive work for students of all grades.

The Open-air Treatment of Tuberculosis.

A meeting of subscribers to the proposed sanatorium for consumptives in Ayrshire was held to discuss the advisability of proceeding with the proposal. The chairman stated that over £12,000 had been subscribed to the building fund, that building plans had been prepared, and that a site had been secured at Glen Afton, New Cumnock. The committee thought that as other sanatoriums erected for the working classes had not been so successful as had been anticipated the subscribers should have an opportunity of deciding whether the plans were to be proceeded with or not. Dr. W. Frew of Kilmarnock proposed that they should proceed with the building and on a show of hands this was carried by a large majority. As regards the upkeep of the institution after erection it was expected that patients or their friends would contribute a little and it was hoped that parish councils and benefit societies would see that it was to their interest to support an institution of this nature.

Cruelty to Children.

During the month of March the Glasgow committee of the National Society for the Prevention of Cruelty to Children investigated 146 cases of reported cruelty involving the welfare of 432 children. The average income of the families was 24*s.* 3*d.* per week but in most instances the father was so lazy or drunken that he contributed nothing to the family upkeep. During the month 722 meals have been given, 28 children have been clothed, and 62 children have been admitted at the children's shelter.

April 11th.

IRELAND.

(From our own Correspondents.)

The Teaching of Sanitary Science in Dublin.

There is a strong movement in Dublin which has for its object to induce the Department of Agriculture and Technical Instruction for Ireland to form a public health museum as an aid to the spread of the knowledge of hygiene. Many public bodies have passed resolutions in its favour—the public health committee of the corporation, the Dublin Sanitary Association, the Dublin branch of the Association for the Prevention of Tuberculosis, the Royal Institute of Architects, &c. It is thought that if a teaching department in public health was founded in connexion with the new College of Science, the foundation stone of which was laid two years ago by the King, the subject of sanitation would obtain a better basis in this city. Professor Antony Roche recently delivered a very successful course of lectures to sanitary inspectors in connexion with the department.

Irish Medical Association.

The now famous report of Surgeon-General G. J. H. Evatt is still the chief topic of interest amongst medical men in Ireland. The following letter from him was published in the daily journals of April 4th :—

> Sir,—The annual meeting of the Irish Medical Association will take place during the ensuing summer at Killarney. I wish to suggest that it seems desirable that so important a gathering of Irish medical men should not devote themselves solely to questions of pay, organisation, and worldly betterment, but that some scientific and technical work should be done. I suggest a discussion on the causes of the pulmonary consumption that so gravely affects the Irish people; further, that some steps be taken to form a representative Sanitary National Council of Irish doctors; and, lastly, that some consideration of the serious lunacy question in Ireland is desirable. It seems to me a pity that the scientific side of Irish medical life, which the Association was formed to develop amongst other things, should, so far as the I.M.A. is concerned, have for many years dropped into abeyance. The time seems now ripe for its revival. Yours, &c.,
>
> George J. H. Evatt.
>
> Junior United Service Club, London, April, 1905.

Surgeon-General Evatt does not seem to be aware that his recent crusade resembled that of "Peter the Hermit" and that the Irish Medical Association when it meets at Killarney during the summer—if it meets at all—will have enough to do in settling its own dissensions. It will certainly have no time on that occasion to cultivate the cool atmosphere of science.

Rainfall in March.

March in Ireland was a wet month with none of the proverbial dust. Rain fell in the neighbourhood of Belfast on 29 days to the amount of 3·92 inches, giving a total of 9·14 inches for this year. The average rainfall in March is 2·93 inches.

The Treatment of Consumptives in Belfast.

The public health committee of the corporation of the city of Belfast has decided that the present time is inopportune for the council to embark on a comprehensive scheme for the treatment of consumptives involving not only a large capital outlay but an annual expenditure which would of necessity considerably increase the ratepayers' burdens. The council is shortly to discuss the question of adopting some modified plan.

Salicylic Acid in Ginger Wine.

At Moville sessions, co. Derry, several people were summoned for selling ginger wine adulterated with salicylic acid. Evidence that this drug as a preservative was dangerous and also that as a preservative in small doses to constitute a temperance drink it did no harm having been given, the magistrates unanimously decided to dismiss the cases.

The Water-supply of Belfast.

The chairman of the Belfast water board at a meeting on April 6th pointed out that although the rainfall at the several works had been slightly below the average yearly quantity all demands during the coming summer months would be supplied as at the present time the reservoirs contained over 200 days' supply of water. During the past season when in many cities in the kingdom an intermittent or short supply for certain hours daily had had to be resorted to owing to the threatened want of water, due largely to the inefficient rainfall, over the entire city area of Belfast, and even in the areas beyond the city supplied by the commissioners, water had been distributed and maintained under high pressure without any interruption whatever.

Belfast District Lunatic Asylum.

At a meeting of committee held on April 10th the medical superintendent reported that in the financial year just closed the gross expenditure had been reduced by £1702 13*s.* 2*d.* as compared with the previous 12 months though the numbers maintained had increased by 27.

April 11th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Scopolamine as an Anæsthetic.

AT the meeting of the Surgical Society held on March 29th M. Terrier related the case of a woman who suffered from unilateral pyonephritis together with an extremely sensitive bladder. M. Terrier tried in vain to ascertain the condition of the urine coming from the other kidney by the use of a separator but neither that of Luys nor that of Cathelin could be borne for more than a few minutes on account of the acute pain which their introduction produced. M. Terrier then thought of trying scopolamine anæsthesia and one injection produced a profound sleep during which all that was necessary in the way of introducing the separator and leaving it in place was successfully carried out. On awaking the patient declared that she had not undergone any operation.

Pulsating Arterial Tumours of the Parotid Region.

At the same meeting of the Surgical Society M. Tuffier discussed the treatment of the above mentioned tumours. He reminded his hearers that the facial nerve generally crossed the field of development of the tumour and was a serious obstacle to its ablation. He said that other methods of treatment were necessary and cited three cases in support of his argument. The first was in a child, aged two years, in whom fou

a cure. The second

who was afflicted w

the whole of the

artery and also wit

in which tumour there was a souffle but no thrill. Pressure on the external carotid artery caused the disappearance of the souffle. Electropuncture having proved useless, M. Tuffier decided to tie the artery and to obliterate the tumour. The artery was exposed and the ligature was passed underneath. Having assured himself that tightening the ligature stopped the souffle M. Tuffier left it in place without tying it. He then encircled the tumour with the ring-handle of a key which compressed the periphery and injected into it six drops of Piazza's solution. The ligature was then tightened and the patient has been perfectly well for the whole of the one year since the operation. The third patient had an erectile tumour in which were present both souffle and thrill and in addition epileptiform attacks had occurred upon more than one occasion. M. Tuffier performed an operation similar to that practised in the last case and the patient has remained well since the operation which was performed two months ago. M. Tuffier concluded by saying that his results showed that injection of the tumour should accompany ligature of the artery seeing that the latter procedure was by itself inefficacious.

Dust on the Roads.

Dust is every day figuring more largely in questions of hygiene. Not only is it harmful to the respiratory passages but it is to a marked degree a disseminator of microbes. The researches of M. Miquel have shown that epidemic diseases are most prevalent in Paris at that season of the year in which dust is most troublesome and, moreover, the routes frequented by motor cars have become absolutely uninhabitable, especially in the Midi. At the meeting of the Academy of Medicine held on March 28th M. Josias read an account of some researches which he had undertaken into the relative value of the various methods in use for the prevention of dust. None appeared quite satisfactory. Tar has marked antiseptic effects, for at a distance of ten centimetres above a tarred road there are found two-thirds less microbes than in the case of a road not so treated. This condition, however, only lasts for a few hours after the tarring has taken place Moreover, tar is costly, it must be frequently renewed, the roadway must be good, and plenty of sunshine is needed. Finally, if the tar is applied on a gradient of about 1 in 33 horses slip on it. Petroleum and heavy oils have an action less lasting than that of tar and their antiseptic power is very feeble. Westrumite is fairly cheap but its action is uncertain in duration, probably not more than a week. Moreover, roads treated with westrumite are very liable to get covered with moulds.

The Relations between Arterial Pressure and Pulmonary Ventilation during Chloroform Anæsthesia: The Influence of Rapid Breathing upon the Occurrence of "Accidents."

M. Tissot has undertaken some researches on dogs with a view to the study of the above subjects. He states that the temporary augmentation of the arterial pressure which is produced at the beginning of the stage of excitement in chloroform narcosis is not due, at least in the majority of cases, to a peripheral vaso constriction but to the well-known influence upon the arterial pressure of the exaggeration of the respiratory movements and to the increase in their amplitude. The succeeding rapid fall in the arterial pressure which accompanies the stage of excitement is not due to peripheral vaso dilatation but *solely to a rapid intoxication of the heart* or of the cardiac centres provoked by the rapid breathing (*polypnée*). The period of excitement is not dangerous in itself but only on account of the rapid breathing which accompanies it and the rapid intoxication which results. Finally, the method of anæsthesia which consists in administering known quantities of chloroform and air in the proportion of 8 per cent. and upwards (*mélanges titrés de chloroforme à 8 pour 100 et au-dessus*) is one likely to give rise to a catastrophe (*méthode sidératrice*). M. Tissot has arrived at the two following conclusions: (1) a long period of excitement is preferable to a short one, for the former does not give rise to dangerous intoxication, and (2) the whole period of hyperpnœa is dangerous and during this stage the anæsthetic must be administered with caution.

The Antiseptic Properties of Certain Vapours.

At the meeting of the Society of Biology held on March 28th M. Trillat read an account of some researches which he had made demonstrating that the vapours disengaged by the combustion of certain substances, notably sugar, the resins, and aromatic plants, contain a notable proportion of formic aldehyde, thus testifying to the wisdom of the ancient custom of burning these substances with a view to disinfection. The vapour produced by the combustion of two grammes of sugar in a bell jar of 12 litres capacity disinfected in 30 minutes various objects infected by the bacillus coli, the bacillus typhosus, the vibrio choleræ, the bacillus tuberculosis, and the like. The staphylococcus aureus was rendered sterile in one hour and the bacillus subtilis in four hours.

Closing of the Paris Faculty of Medicine.

In a recent article I mentioned the disturbances which have been taking place at the Faculty of Medicine in connexion with the lectures of M. Gariel and the noisy demonstrations that have been made outside his house. The students have not been appeased by the letter of apology addressed to them by the Prefect of Police and have persisted in their unruly behaviour. At M. Gariel's last lecture M. Debove, dean of the Faculty of Medicine, hoping to say something which would have a pacifying effect, entered the lecture room in company with the unpopular professor. More than 500 students who were already assembled there received M. Debove and M. Gariel with such an uproar and shouting that the two professors had to withdraw without having been able to say a word. M. Debove thereupon reported the circumstances to the University council and to M. Liard, the vice-rector. The council was in favour of closing the Faculty and M. Bienvenu-Martin, the Minister of Public Instruction, ordered it to be closed, considering that the students, instead of acting as they had done, might have sent representatives to the dean with a statement of their grievances. The school will be reopened on May 1st. The students have naturally protested, for this measure may have serious results for some of them—those, namely, who are approaching the age limit for military service. In France medical students have only one year of military service provided that they complete their medical studies before attaining the age of 25 years, failing which they must make up the other two years of military service. This closure of the school for nearly a month will delay a good many of the students by preventing them from being ready for the next examinations and may be the means of compelling them to serve the two extra years. The importance of the step that has been taken is therefore obvious. The medical students are having complaints made both in the Chamber of Deputies and in the Senate. It is to be hoped that this unfortunate incident may soon be at an end and that a way out of the difficulty may be found for the young men who are near the age limit.

April 11th.

NEW YORK.

(From our own Correspondent.)

The Increase of Cerebro-spinal Meningitis in New York.

The statistics of the New York department of health up to March 31st showed that cerebro-spinal meningitis had increased and was still increasing. For the four and a half days ending noon, March 30th, from midnight, March 26th, there had been 104 deaths, as compared with 85 for the entire previous week. Statistics tabulated by weeks showed that the progression of the disease as evidenced by its death-rate was 27, 40, 48, 62, 78, 72, and 85, as against the total of 104 for the four days up to noon, March 30th. The disease is also on the increase in the neighbouring towns and considerable public apprehension has been expressed.

Hospital Finances in New York City.

The hospitals of New York are in the plight of some of your best known London hospitals financially; in fact, for some years they have been going from bad to worse in this respect. So serious is the situation considered that a public meeting has been held recently under the auspices of the New York Association for the Improvement of the Condition of the Poor in order to devise means by common action to secure more support for the hospitals and to discuss the question of hospital finance generally. The meeting was very largely attended, each hospital in the city having sent three delegates. Mr. Frank Tucker, in the course of a speech, said that the public should be educated to give more, that the hospitals should be managed more economically, and that enlarged facilities should be secured by the hospitals through inexpensive house-to-house visiting rather than through the establishment of more wards. Dr. John S. Brannan of Bellevue and allied hospitals condemned in sweeping terms the wasteful methods employed in New York hospitals. "Our American system," he said, "is all right from the point of view of training physicians and nurses, but all wrong from the point of view of hospital administration."

A Disgrace to the Medical Profession: the Radium Swindling Case.

Dr. Henry H. Kane and Dr. William H. Hall, the two medical men who were indicted through the agency of the New York County Medical Society for swindling in connexion with so-called "radium cures," have pleaded guilty and have been sentenced. Kane received four months and Hall eight months in the penitentiary. I described the case some few weeks ago in The Lancet. Kane and Hall, it may be remembered, induced a carpenter to give them $9780 (£1956) on the pretence that they would cure him of Bright's disease by means of radium. Clemency was recommended for the men owing to the fact that they had made restitution to the carpenter of the full amount.

The Management of the Panama Canal.

A report to the Government of the United States by Dr. Charles A. L. Reed, published in the *Journal of the American Medical Association* of March 11th, has created somewhat of a sensation in the country. Dr. Reed, although not in the canal zone in a medical official capacity, had been requested by the Secretary of War to make a report of his observations relative to sanitation and the work of the sanitary department in that zone as well as in the cities of Colon and Panama. His report is an extremely severe indictment of the Isthmian Canal Commission, which was nominated by President Roosevelt on Feb. 29th of last year and is likely to be replaced by another authority within the next few days. The composition of the sanitary department is excellent and no man more fitted for the post of its head could be found than Colonel Gorgas, but Dr. Reed asserts that its work is so hampered by the civil authorities as in many respects practically to be nullified. The health department of the canal zone has been subordinated to such a degree to the commission that the former cannot perform its duties properly. The campaign against yellow fever and malaria has been thwarted, according to Dr. Reed, by the actions of the commission. A point sharply criticised by Dr. Reed is the meagre pay offered to physicians for their services in the canal zone. Colonel Gorgas had recommended that the minimum salary to be paid to medical men in the canal zone should be the same as the minimum salary in the army for contract surgeons, $1800 (£360) a year, but this rate of payment did not commend itself to the commission which thought that $50 (£10) a month were sufficient. Dr. Reed contends that so small a salary, taken in connexion with the unhealthy climate, will not attract able men and that only what he terms "cheap surgeons" will go to Panama for such a wage. Dr. Reed's critical remarks have caused a stir throughout the country. Since the publication of Dr. Reed's report, the report of Colonel Gorgas has been issued. From this report it is gathered that the sick employés of the United States Government in the canal zone during February, 1905, numbered 151, a percentage of less than 2, and the number of deaths nine, which is equivalent to a rate of 14 per 1000 per annum. The last case of yellow fever to occur in Panama was on March 18th. The total number of cases among the entire population on the isthmus during January was 19, during February 13, and during March up to date nine. The present sanitary force consists of over 1000 employés, costing over $25,000 monthly. President Roosevelt rebuked Dr. Reed for the manner in which he framed his report and made it public at the time that he did. It is clearly recognised that sanitation is the paramount consideration in the Isthmus of Panama at the present time and it is generally felt that Colonel Gorgas should have a free hand. The late Major Reed and he did such splendid work in Havana that although the situation is worse in the canal zone there would seem to be no reason that, unhampered by unnecessary restrictions, the results should not be successful there.

The First Pavilion of the New Bellevue Hospital.

At a meeting of the New York board of estimate and apportionment held on March 16th an appropriation of $850,000 (£170,000) was made, to be employed in the construction of the first pavilion of the new Bellevue Hospital. This pavilion will be erected in the grounds of the present buildings and will have a capacity of 350 beds and when completed will relieve the congested condition of the old institution. The new structure is to be built in sections as the money is forthcoming at an estimated cost of $10,000,000 (£2,000,000) and when finished will accommodate 2000 patients.

April 3rd.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

The Plague.

BUBONIC plague continues to claim a number of victims in Queensland. Up to Feb. 27th 19 cases had been verified since the reappearance of the outbreak. During the last week four deaths have occurred. As regards the outbreak on the Clarence river in New South Wales the President of the Board of Health (Dr. J. Ashburton Thompson) claims that "the campaign of his department against it has been unusually successful." Six cases occurred before any report was made. Between Jan. 7th and 27th six more patients were attacked. Up to Feb. 27th no further cases have occurred. The last plague-infected rat was found on Feb. 26th. A deputation from Grafton protested to the Acting Premier against plague patients being treated at the general hospital at Grafton. The Acting Premier replied that he had discussed the matter with the President of the Board of Health who said that no alteration could possibly be made with regard to the patients at present in the Grafton Hospital. [illegible] as infec[illegible] plague [illegible] outbreak plague patients were treated in the same wards as ordinary patients at the Coast Hospital and as a matter of medical practice no attention was paid to communicability. The President of the Board of Health has also been communicating to a Sydney newspaper his views on plague generally. He remarked that the official methods in India and Egypt had conspicuously failed because they did not, as was done in New South Wales and other countries, recognise the rat as the sole source of danger.

Vital Statistics of Sydney.

The Government statistician's report for the year 1904 has been issued for Sydney. The birth-rate was 25·67 and the death-rate 11·02 per 1000 [illegible] births over deat[illegible] year is, on the [illegible] higher than for any year of the decennium. Relatively to population, although not so high as in 1897, they were higher than the average which has prevailed since that period. The illegitimate births, 1343 in number, formed 10·16 per cent. of the birth list. This rate exhibits a slight increase on that for 1903, which was 10·02. The death record is extremely satisfactory, since, when allowance has been made for increase in population, the death-rate of 11·02 per 1000 is 7 per cent. below the average of the preceding five years. The infantile death-rate is well below the average, being at the rate of 98 per 1000 births, as against 123, the average rate for the last ten years. Of persons aged 70 and upwards there were 926 deaths (435 males and 491 females). They were of the following ages: 649 ranging from 70 to 79, 250 from 80 to 89, and 26 from 90 to 99. As regards the causes of death, the decline in the rate was general in nearly every class, the exceptions being among constitutional and developmental diseases and those of the urinary system. Making allowance for the increase in population the rate was only 80 per cent. of the average prevailing during the previous five years. The returns of the Department of Health show that 665 cases of illness from typhoid fever, [illegible] ses of scarlet fever were [illegible] nbers, when compared [illegible] give fatality results of 9·9, 5·7, and 1·0 per cent. respectively. In the constitutional diseases there is an advance in each of the great divisions of the class, cancer (382) and phthisis (523) exhibiting numerical increases of 6 and 2 per cent. respectively as compared with the quinquennial average. This advance, of course, appears in much moderated force when allowance is made for the increased population.

A Medical Naval Reserve.

The naval commander-in-chief of the Australian station proposes to form a medical naval reserve to [illegible] surgeons in the event of hostilities arising. He has written to the branches of the British Medical Association in the several States asking them to take the matter up in conjunction with the medical schools' authorities and to enlist the sympathy and assistance of the members of the medical profession.

Hospital Affairs.

The Inspector of Charities recently stated that in his opinion the cost of maintenance per bed at the Melbourne Hospital was too high in comparison with other hospitals. A subcommittee was appointed to inquire into and to reply to the statement of the inspector. It has reported that the cost was due mainly to three causes: 1. The building was old and out of date, requiring constant repairs in plumbing, roofing, &c., which last year cost £850. The various wards being on different levels and unconnected and without lifts a large staff of porters was necessary. 2. The large number of patients treated and operations performed, 1770 operations last year as against 700 at the Alfred Hospital, with which comparison was chiefly made. 3 The increase in the nursing staff from 70 to 92, made by order of the Government and against the wish of the nurses themselves. Further, the hospital being a clinical school added to its expenses.—A question of internal discipline has recently taken up the time of the committee of the Melbourne Hospital. One of the sisters in charge of a ward made some remarks in her ward book about the use of sterilised gauze which were supposed to imply a reflection on another sister and she was ordered by the matron to expunge the remarks. She refused and was deposed from her position and given other duties which she declined to do. She was then suspended by the matron and told to resign. As she did not do so she was dismissed. She appealed against the dismissal on the ground that her original statement was correct and the matter of the greatest importance, the use of unsterilised gauze imperilling the lives of the patients. The committee upheld the action of the matron and confirmed the dismissal.—The Women's Progressive Association of New South Wales at its last meeting decided to call the attention of the Premier to the unjust method of selection exercised by the hospital boards of the Sydney and Royal Prince Alfred Hospitals in making appointments to the resident medical staff a question of sex instead of qualification and to ask him to use his influence to have a fairer system adopted in the future.—Although diphtheria and scarlet fever are far from absent in the metropolis of Melbourne the Infectious Diseases Hospital is almost empty and the medical superintendent has reported that the staff was too large for the requirements. As previously pointed out, the admission of patients is so hampered by red-tape regulations that people will not make use of the institution, which is also very inaccessible.

Dr. A. D. Leith Napier's Claims for Compensation.

Dr. A. D. Leith Napier, who some years ago was brought to Adelaide by the Government as medical officer to the Adelaide Hospital, was subsequently appointed surgeon to the second contingent of troops sent to South Africa. In January, 1900, while riding to Marino, he was thrown from his horse and fractured his skull. He recently brought an action in the Supreme Court to recover £6500 compensation from the Government. The Chief Justice held that as the plaintiff was not on actual service when the injury happened he was not entitled to compensation and gave a verdict for the defendants.

March 8th.

Obituary.

JAMES ALEXANDER, A.B., M.D., M.CH. DUB.

Dr. James Alexander died at his residence, Paignton, South Devon, after a short illness, from pneumonia, on April 2nd in his fifty-eighth year. The deceased graduated M.B., M.Ch. of the University of Dublin in 1869, taking the M.D. degree in 1878. Dr. Alexander had been for many years in practice at Paignton. He was surgeon and agent to the Admiralty at Paignton and also surgeon to the post office. He was one of the most popular men in the neighbourhood and was connected [illegible] very social and philanthropic [illegible] town. For some years he was chairman of the Paignton school board and since its dissolution a member of the higher education committee. In politics he was a Unionist and had been on several occasions president of the local constitutional club. He took the greatest interest in all forms of sport and there was scarcely a sporting club in Paignton of which he was not president or vice-president. Dr. Alexander had a large practice and last summer was elected president of the South-Western branch of the British Medical Association, when he entertained the members and delivered an able presidential address. Dr. Alexander will be much missed in Paignton, especially by the poor to whom he was an unfailing friend.

VISIT OF BRITISH PHYSICIANS AND SURGEONS TO PARIS.

WE publish below the official programme of the proceedings arranged by the Paris Executive Committee for the entertainment and instruction of the British physicians and surgeons who are next month to pay a return visit to our French colleagues.

PROGRAMME.

Wednesday, May 10th.—9 P.M.: Reception at the Sorbonne by M. Liard, Rector of the University of Paris, and M. Casimir Perier, ex-President of the French Republic, President de la Société des Amis de l'Université.

Thursday, May 11th.—Morning: Visits to hospitals and laboratories. Afternoon: Visits to the Faculté de Médecine, Assistance Publique, Hôtel de Ville.

Friday, May 12th.—Morning: Visits to hospitals and laboratories. Afternoon: Party to visit Chantilly, now the property of the Institut de France. Evening: *Représentation théâtrale* at the Automobile Club, Place de la Concorde.

Saturday, May 13th.—Morning: Visits to hospitals and laboratories. Afternoon: Visits to the Institut Pasteur and the Hôpital Anglais. Evening: Banquet.

The two following excursions will both leave Paris on Sunday afternoon, May 14th, and return to Paris on Tuesday night, May 16th, or Wednesday morning, May 17th.

1. The companies of Vichy and Evian invite a party of 100 (including ladies) to travel to Vichy, thence to Evian *viâ* Lyons, and back to Paris, all expenses being defrayed by the companies.
2. The Medical Society of Pau and the towns of Arcachon, Biarritz, Salies de Béarn, and Pau invite a party of about 100 (including ladies) to visit these watering places, where they will be received by the municipalities.

The British party will include representatives from provincial centres in England and from Scotland and Ireland.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At the primary examination held recently the following candidates passed in the subjects indicated:—

PART I.

Biology.—H. S. Brown, University College, Nottingham; E. C. R. Fisher, Royal Free Hospital; and F. S. Hawks, King's College Hospital.

Chemistry.—U. J. Bourke, London Hospital; W. E. Dimond, Liverpool; F. S. Hawks, King's College Hospital; and H. H. Smith, Royal Free Hospital.

Materia Medica and Pharmacy.—H. S. Brown, University College, Nottingham.

PART II.

Anatomy.—D. E. S. Davies, King's College Hospital; A. R. Hardy, Manchester; P. J. Lush, London Hospital; [illegible] College Hospital; P. D. Pickles, Leeds; C. [illegible] E. F. Waddington, Leeds; and M. V. Webb [illegible]

Physiology.—F. M. Cunningham, Royal Free Hospital; D. E. S. Davies, King's College Hospital; A. R. Hardy, Manchester; O. Marshall, University College Hospital; P. D. Pickles, Leeds; C. S. Spencer, Manchester; and M. V. Webb, Royal Free Hospital.

UNIVERSITY OF ABERDEEN.—The following degrees in medicine and diploma were conferred on April 7th:—

Degree of Doctor of Medicine (M.D.).—Robert Grant, Chatham; Andrew Ross Laing, West Cults, Aberdeen; and Alexander Ledingham, Hamilton.

Degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.).—With Second-class Honours: Robert Brown. *Ordinary Degrees:* Mary Ronald Bisset, Alexander Brown, Duncan Coutts, A. Dawson, Walter Allen Elwood, W. Gordon Gordon, William Low, James Breadalbane Macdiarmid, James Edward Mennie, Alexander Mitchell, John Proctor, W. Ewen Reid, John Sangster, James Archibald Bruce Sim, Robert Haig Spittal, John Maxwell Taylor, and Lisette Anne Macdonald Wilson.

Note.—Francis William Falconer has passed all the examinations but wi[illegible] has attained the necessary age.

[illegible] *lth.*—William Anderson, M.B., Ch.B. Aberd., [illegible] mieson Pirie, M.B., Ch.B. Aberd., Orkney; [illegible], M.B., Ch.B. Aberd., Elgin; and Herbert W. Black Ruxton, M.B., Ch.B. Aberd., Ellon.

UNIVERSITY OF OXFORD.—Mr. Arthur F. Hertz, M.A., M.B., Magdalen College, has been elected to a Radcliffe Travelling Fellowship for three years.

DEATH OF A CENTENARIAN.—The *Times* of April 10th states that Miss Tyler, the oldest inhabitant of Durham, died on April 8th. She completed her 100th year in December, 1904.

VACCINATION GRANT.—Mr. W. H. Hubert, M.R.C.S. Eng., L.S.A., has received the Government grant for successful vaccination in the Shipley district of the Horsham union, Sussex.

ST. JOHN AMBULANCE ASSOCIATION.—In the Brunswick Institute, Wandsworth-road, London, S.W., on April 5th, the London and South-Western railway team of Queen-street, Exeter, won the challenge shield, valued at £50, and each of the five members of the team received a silver medal.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The election of examiners will be held on Tuesday, May 2nd, as follows:—Two examiners in anatomy, four in surgery, two in physiology and histology, two in pathology and bacteriology, one examiner in midwifery and gynæcology, one in biology, two examiners in ophthalmology, one examiner in sanitary law and vital statistics, one in engineering and architecture, two examiners in chemistry and physics, two in dental surgery and pathology, two in mechanical dentistry, one examiner (not being a Fellow or Licentiate of the College) in languages, and one (not being a Fellow or Licentiate of the College) in mathematics, physics, dictation, and English essay. Candidates are requested to lodge their applications in writing with the registrar, at the College, on or before Tuesday, April 25th, at 10 A.M.

ROYAL INSTITUTION.—The following are the lecture arrangements at the Royal Institution after Easter:—Professor L. C. Miall, Fullerian professor of physiology, R.I., three lectures on the Study of Extinct Animals; the Rev. H. G. Woods (Master of the Temple), three lectures on Velasquez; Professor Sir James Dewar, Fullerian professor of chemistry, R.I., three lectures on Flame; Professor J. A. Fleming, three lectures on Electro-magnetic Waves (the Tyndall lectures); Professor H. Marshall Ward, two lectures on Moulds and Mouldiness; Dr. J. G. Frazer, two lectures on the Evolution of the Kingship in Early Society; and Mr. A. H. Savage Landor, two lectures on Exploration in the Philippines. The Friday evening meetings will be resumed on May 5th, when a discourse will be delivered by Professor H. E. Armstrong on Problems underlying Nutrition. Succeeding discourses will probably be given by Professor E. Fox Nicholls, Sir Charles Eliot, K.C.M.G., Professor J. W. Bruhl, Mr. George Henschel, and Sir William H. White.

HOSPITAL MISMANAGEMENT IN RUSSIA.—A local correspondent of the *Novoe Vremya* makes serious charges against the management of the infirmary in Nikolaieff, a large town in the south of Russia. He says that the infirmary is so overcrowded that patients have to sleep in the corridors. Bags stuffed with straw are used as mattresses and the pillows are also stuffed with straw. The supply of linen is so scanty that what is in use cannot be changed and the same beds are occupied successively by infectious and non-infectious cases without removal of the bedclothes. Two or three patients bathe in the same water. The water-closets are only supplied with water in the morning, washhand basins are placed in them, and ice for the use of the patients is broken there. Knives and forks are not provided for the patients who have consequently to eat with their fingers, but strange to say the wards are fairly clean, well lighted, and well ventilated. One of the infirmary servants, inspired by benevolent motives, is in the habit of collecting the food which is left by the patients in order that he may distribute it among the poorer classes who live in lodging-houses. As many of the patients suffer from typhoid fever there is an obvious risk of spreading infection in this way and the correspondent expresses the opinion that the practice ought to be stopped.

DONATIONS AND BEQUESTS.—The honorary treasurer of the Southport Convalescent Hospital and Sea Bathing Infirmary has received a cheque for £5000 from the trustees of the late Mr. James Holden of Rochdale towards the endowment of the hospital, in consideration of which five beds are allocated in perpetuity for the use of convalescents from Rochdale and district.—Lord Derby has started a bed endowment fund for the Royal Sea Bathing Hospital, Margate, by contributing a donation of £1000 for the endowment of the first bed.—The Duchess of Somerset has sent £150 to the funds of the Alexandra Hospital for Children as the result of a concert held at 35, Grosvenor-square on March 30th.—Mr. W. R. Merry of Exeter has given £100 each to the Royal Devon and Exeter Hospital, the West of England Institution for the Deaf and Dumb, the West of [illegible]

bequeathed £500 each to the Royal Devon and Exeter Hospital, the West of England Eye Infirmary, and the West of England Blind Institution, and £300 to the West of England Institution for the Deaf and Dumb.—Sir George White, Bart., of Bristol has given a donation of £3000 to secure the completion of the Victoria Memorial Hospital, Nice.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Physical Deterioration.

AT the evening sitting in the House of Commons on Tuesday, April 18th, Mr. SLACK will open a debate on the report of the Inter-Departmental Committee on Physical Deterioration and will propose a motion.

HOUSE OF COMMONS.

WEDNESDAY, APRIL 5TH.

The Administration of Poison by Misadventure.

Sir THOMAS DEWAR asked the Home Secretary whether, having regard to the frequency of suicides by poison and loss of life through [illegible]

[illegible] I gave to the honourable Member on March 15th last.

A Post Office Case.

Sir WALTER FOSTER asked [illegible] he was aware that a telegraphist na[illegible] tificate from a private medical atte[illegible] he was suffering from post-influenza [illegible] rest; that the official medical adviser certified that Bullamore's health was as usual and no rest was required; that subsequently a specialist [illegible] and that he [illegible] and that [illegible] of the s[illegible] that his [illegible] titioners. [illegible] respectin[illegible] and from [illegible] the Post Offic[illegible] I have dec[illegible] the whole ma[illegible] certificat[illegible] to them, bu[illegible] officers o[illegible] the medical referee is consulted.

The Adulteration of Butter.

Mr. BRIGG asked the President of the Board of Agriculture what [illegible]

THURSDAY, APRIL 6TH.

Coastguard Surgeons in Ireland.

Mr. O'CONOR KELLY asked the Secretary to the Admiralty whether he would state the number of coastguard surgeons in Ireland; how many held appointments additional to the Admiralty one; and how many devoted themselves exclusively to Admiralty work.—Mr PRETYMAN said: The number of Admiralty surgeons and agents in Ireland is 117. These gentlemen are not required to devote themselves exclusively to Admiralty work.

Civil Surgeons and Income Tax.

Mr. O'DOHERTY asked the Chancellor of the Exchequer whether he was aware that civilian surgeons attached to His Majesty's forces in [illegible]

The Treatment of Cases of Sudden Illness in the House.

[illegible] the House. No answer was given.

Drumconrath Medical Relief Dispensary.

Mr. JOSEPH NOLAN asked the Chief Secretary for Ireland whether his attention had been drawn to the action of the Local Government Board in proceeding by sealed order to suppress the Drumconrath [illegible] that under the new [illegible] least 10 or 12 miles [illegible] whether, in view of [illegible] the protest of the [illegible] the division affected [illegible] the Local Govern[illegible] replied: The Drum[illegible] adjoining districts of [illegible] the residence of the [illegible] within a reasonable [illegible] is satisfied that no [illegible]

Starving School Children.

Dr MACNAMARA asked the First Lord of the Treasury whether his attention had been called to the Bill to provide, under proper safe[illegible] or is not of [illegible] of the country [illegible] country.—Mr. [illegible] of the underfed [illegible] mittee to give [illegible] think we ought [illegible]

FRIDAY, APRIL 7TH.

Mr. O'DOHERTY ask[illegible] rules regarding the [illegible] on the first of each month and at other times [illegible] in the opinion of the resident [illegible] proper matter are submitted by [illegible] and are dealt with by them [illegible] letters recently written by the [illegible] resident physician and governor [illegible]

MONDAY, APRIL 10TH.

[illegible] stated that a [illegible] for use in [illegible] duty who was [illegible] duly authorised [illegible]

A Question Concerning Horseflesh.

Mr. CREMER asked the Under Secretary of State for Foreign Affairs whether he was now in a pos[illegible] which in August last year he [illegible] number of old and slaughtere[illegible] were periodically exported f[illegible] and Germany; whether he c[illegible] were used; and whether their flesh was made into condiments of various kinds, returned to this country, and sold as articles of food.—Earl PERCY answered: I regret that owing to an oversight some delay occurred before the information was asked for but we hope to obtain it before very long.

Dow.—On April 8th, at High-street, Lewes, Sussex, the wife of W. A. Dow, M.D., of a son.

Dowsett.—On April 5th, at St. Dunstan's, Lebanon-park, Twickenham, the wife of Ernest B. Dowsett, M.R.C.S., L.R.C.P., L.D.S., of a daughter.

Knight.—On April 7th, at The Turret, Streatham High-road, S.W., the wife of G. David Knight, M.D., of a daughter.

Unitt.—On April 10th, at Quorn, Loughborough, the wife of J. A Unitt, L.R.C.P., M.R.C.S., of a son.

MARRIAGES.

Herring—Callender.—On April 7th, at St. James's United Free Church, Edinburgh, Perc [illegible] F.R.C.P.E., to May, elder daughter of [illegible] nburgh.

Hutton—Smart.—On April 1 [illegible] Glasgow, William Kilpatrick Hut [illegible] an Elder Symington, daughter of W [illegible]

DEATH.

Truman.—On April 8th, at The Home Field, Putney-hill, Edwin Thomas Truman, M.R.C.S., of Old Burlington-street, W., in his 87th year.

N.B.—A fee of 5s. is charged for the insertion of Notices o Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

POLICE CALLS FOR MEDICAL MEN.

WHAT was described as an [illegible] came up for discussion at a recent [illegible] standing joint committee The c[illegible] reported that Dr C. Pollard of Worcester had sent in a claim for a fee of 7s 6d. for attending a case of suicide Last November a man who had cut his throat just outside the city was found by a constable at midnight and Dr. Poll[illegible] he arrived the man wa[illegible] now applied for his fee [illegible] the county to pay a fee [illegible] before death and therefore he declined to pay. He had received a letter from the Medical Defence Union stating that the inquest fee had nothing to do with the charge for the midnight visit There was an underlying professional principle affecting the matter which had induced the council of that union to take it up and it gave notice that unless the payment was made it should take proceedings for its recovery. Dr. H. E. Dixey, a member of the committee, said that the two attendances were quite separate and he thought that the money should be paid. If the man had died immediately after the medical man arrived they would have paid without demur and he thought it straining the point to refuse As the medical man had to leave his bed at midnight he considered the fee very reasonable; it might justly have been half a guinea. Mr. Pritchett thought that the fee given at the inquest ought to be held sufficient payment. If the medical profession were not satisfied with the fees paid under the Coroners Act they should endeavour to get them increased. After further discussion the chief constable said he thought that they were liable Objection was taken to the payment on *the ground that it was undesirable to establish a precedent* Eventually, by six votes to five, it was decided that the money should be paid.

THE LORD OF THE MANOR'S HERIOT AT AN INQUEST.

To the Editors of THE LANCET.

SIRS,—Your correspondent, Mr W. H. Marsden, must obviously be right in his suggestion that the "stagg" forfeited as deodand in the case quoted by Dr. J. J. Udale was the horse which caused the injury—perhaps the word is connected with the more familiar "nag." A stag conceivably might be forfeited if it caused death when kept in confinement, but otherwise it could hardly be the subject of "deodand" or "heriot." I take it that in 1794 stags in Westmorland were pretty universally both legally and in fact animals *feræ naturæ* and not the subject of ownership by anyone, still less by anyone who was liable to forfeit either deodands or heriots to Lord Lonsdale

I am, Sirs, yours faithfully,

April 10th, 1905 A

THE CLERGY AND QUACKS

THE following [illegible]

[illegible] is not given and it is dated from Clifton, Jan. 1st, 1802 "... Look into whatever newspaper you please, you will find reverend names, dangling by dozens, to the tails of frauds at *half a guinea the bottle.* I would fain hope that the appearance of these names, in such a disgraceful position, does but add one item more to the advertisers' account of forgery. I, at least, for one, am unwilling to believe, that so many members of a respected profession can lend or let out their credit for a fox's paw, to rake the pockets of the poor, whose money, however ill they can spare it, is often the least valuable thing, out of which, from reliance on the judgement of the clergy, in many cases they [illegible]

a [illegible] cently came a [illegible] ril 12th there a [illegible]

> J. P. SANDLANDS, Author of "The Voice and Public Speaking," "The Microbe," "Disease," "Cancer" (which means no more "Cancer Research"), &c, and Specialist in "Throats," Chest, Nerves, Cancer, and Dietetics, may be CONSULTED between 3 30 and 5 30, Saturdays only, at the Midland Hotel, St. Pancras Letters, Brigstock, Thrapston

J. P Sandlands, the self styled specialist, is, we find on reference to the Clerical Directory, the Rev John Poole Sandlands of Brigstock Vicarage, Thrapston We may remark that being ordained to the cure of souls is not the same thing as being ordained to the cure of bodies, and although we cordially approve of the clergy taking an interest in the sanitation of their parishioners, it is not becoming that they should act as quack "doctors" at a metropolitan hotel We think that the Rev. John Poole Sandland's Bishop might well hint to him that such conduct is unbefitting a clerk in holy orders.

"IN HOSPITAL," BY A PATIENT.

IN England, where so many people find an outlet for superfluous energy or unoccupied time in the propagation of guilds and societies for all sorts of worthy and of trivial purposes, it is a pity that no reformer has yet arisen to start or to lead a crusade for the "suppression of medical matter in non medical magazines" He would have for his society both an alliterative title and a commendable aim The most recent production with which we have been confronted is in the *Grand Magazine* by a "Private Patient" Anyone who wishes to encourage within himself a faint feeling of approaching nausea had better study the pages to which we refer. The writer, a neurotic amateur journalist, it might be imagined from intrinsic evidence, went into the "pay wards" of a London hospital in order to have the appendix removed So far his conduct is from some points of view irreproachable Unfortunately, he sees fit to send to the *Grand Magazine* a detailed account of everything that he remembers of his stay in hospital What useful or beneficial purpose such writing can serve we are utterly unable to perceive It merely panders to a morbid curiosity that is already too fully stimulated by the daily press. It supplies future patients, moreover, with just that little knowledge that is so often dangerous. It gives an exaggerated notion of many slight matters and a minimised idea of others that are important To the non medical reader such effusions must afford chiefly, we imagine, a vague sense of indecency, to the medical reader they offer only a feeling of irritation against the misguided person who writes of what he only partly understands

PARTHENOGENESIS?

THE following advertisement appears in the *Times* of April 12th :—

> MARRIED COUPLE, French, no children, seek SITUATION as LAUNDRYMAIDS in gent 's family. Both thoroughly understand the work in all branches Personal character —J., 42, Marlborough road, Oxford.

It hardly seems necessary for the advertisers to state that they have no children!

DAMMING OF THE THAMES

To the Editors of THE LANCET.

SIRS,—Among the objections to this scheme important medical ones seem to have been overlooked As the Thames at London would cease to be tidal a great cause of the comparative healthiness of that city would also cease—the displacement of air now produced by the tide—and we could anticipate a consequent increase of disease, due, also, to very imperfect flushing by the small stream through a long lake The overflowing of low banks on the Surrey side after storms would lead to insanitary conditions and the increased difficulties of sewerage and drainage would be enormous and costly. If the dam be constructed whence would much of the water supply of London be obtained? and at what cost? None of the water should be drawn from the Thames It would be highly dangerous to drink (unboiled) the polluted fluid taken from the almost stagnant ditch Remember Lincoln The demerits of the scheme outweigh the many advantages, commerce might be enhanced but health would suffer so much that London would become a city to avoid

I am, Sirs, yours faithfully,

Malvern, April 11th, 1905 STANLEY HAYNES, M D. Edin.

DEFECTIVE CHILDREN.

To the Editors of THE LANCET.

SIRS,—Would any member of the profession advise where it is possible to get a governess for a child, aged seven, who is somewhat mentally deficient and requires great care in training A good salary will be given

I am, Sirs, yours faithfully,

G P.

MOSQUITO CURTAINS AND MALARIA.

To the Editors of THE LANCET.

SIRS,—The discovery of Sir H. Arthur Blake that the transmission of malaria by mosquitoes is recognised in Sanskrit literature, referred to in THE LANCET of April 8th, p 973, recalls the following passage in Herodotus which is of some interest in that connexion "The contrivances which they use against gnats wherewith the country swarms are the following In the parts of Egypt above the marshes the inhabitants pass the night upon lofty towers, which are of great service, as the gnats are unable to fly to any height on account of the winds In the marsh country, where there are no towers, each man possesses a net instead By day it serves him to catch fish, while at night he spreads it over his bed in which he is to rest, and, creeping in, goes to sleep underneath The gnats, which if he rolls himself up in his dress or in a piece of muslin are sure to bite through the covering, do not so much as attempt to pass the net" (Rawlinson's Herodotus, vol ii, p 154) It may be inferred from it, however, that the dual advantage of an effective "mosquito curtain" was not then known in Egypt, for no fact so interesting could have escaped the notice of the historian A distinguished orientalist to whom I wrote on the subject kindly informed me that there was not to his knowledge any allusion in Semitic writings anticipating the modern theory, although there are, of course, many to the direct aggressions of insect pests.

I am, Sirs, yours faithfully,

Clifton, April 11th, 1905 D. A. ALEXANDER.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.	£	s.	d.
One Year	£1	12	6
Six Months	0	16	3
Three Months	0	8	2

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminste) should be made payable to THE LANCET Offices, 423, S

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTICE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

ABSTRACT OF

The Hunterian Lectures

ON

THE DISSEMINATION OF MAMMARY CARCINOMA.

Delivered before the Royal College of Surgeons of England on March 13th, 15th, and 17th, 1905,

BY W. SAMPSON HANDLEY, M.S., M.D. LOND., F.R.C.S. ENG.,

HUNTERIAN PROFESSOR; SURGEON TO OUT-PATIENTS, SAMARITAN FREE HOSPITAL; "RICHARD HOLLINS" CANCER RESEARCH SCHOLAR, THE MIDDLESEX HOSPITAL.

LECTURE III.[1]

Delivered on March 17th.

MR. PRESIDENT AND GENTLEMEN,—We now come to the second great division of the subject, the origin of the metastases found in the viscera. There are few forms of carcinoma in which visceral deposits are more frequently met with, or more widely distributed, than in cancer of the breast. Of 329 cases from the records of the Middlesex Hospital, excluding deposits in the axillary glands, metastases occurred in 77 per cent.

SUMMARY OF CONCLUSIONS ON VISCERAL DISSEMINATION.

The time available is short and I shall therefore submit to you at once a concise statement of the conclusions to which my work has led. By thus inverting the subject I shall avoid at the cost of some loss of emphasis the necessity of continually turning aside from facts to inference. It is for you to decide whether the implied inductions are justified. The evidence upon which I rely will be found more fully stated in my Astley Cooper Prize Essay (1904) on "Epigastric Invasion of the Abdomen in Breast Cancer," shortly to be published in the Guy's Hospital Reports.

The great frequency of visceral metastases in cancer of the breast is mainly owing to the extension of cancerous permeation along the fine anastomoses which, piercing the parietes, connect the lymphatic plexus of the deep fascia with the subendothelial lymphatic plexuses of the pleura and peritoneum and with the mediastinal and portal glands. It has already been shown that in parietal dissemination the main factor is centrifugal permeation of the fascial plexus. And in visceral dissemination, too, permeation, especially of the subserous plexuses, plays an essential part. But these plexuses lie close to the serous surface and consequently, in the later stages of visceral dissemination, a factor even more important than permeation comes into play. The dominant factor in visceral dissemination is the escape of cancer cells into the serous cavities, their distribution through those cavities under the influence of gravity and of visceral movement, and their implantation at various points upon the serous surface of the viscera. This process may be spoken of as transperitoneal or transpleural implantation. The occurrence of permeation and of embolic gland invasion from each of the foci thus arising soon terminates the patient's existence. If this outline sketch of visceral dissemination be a correct one it should be possible to show [illegible] be invaded independently of th[illegible] and both for the peritoneal and [illegible] proved: (*b*) that its subserous [illegible] connected by fine anastomoses with the fascial plexus which lies beneath the subcutaneous fat; (*c*) that along these connecting vessels permeation extends from the fascial to the subserous plexus; (*d*) that in consequence cancer cells escape into the serous cavity; (*e*) that these cancer cells are capable of becoming re-implanted at various points on the serous membrane and of thus giving rise to metastases; (*f*) that if the serous cavity is obliterated by adhesions and trans-cœlomic implantation is [illegible] ation is delay[illegible] l metastases is [illegible] origin, and more especially that they primarily affect the surface of the viscera, and that owing to the action of gravity they are found most abundantly at the lower limits of the serous cavities.

CURRENT VIEWS ON VISCERAL DISSEMINATION.

The embolic theory, rather perhaps in default of a rival than upon its own merits, is the accepted explanation of visceral metastases in general (see Lecture I.). I shall attempt to show, not directly but by implication, that for visceral as for parietal metastases the embolic theory is inconsistent with the broad facts, though for isolated cases it is undeniably true.

STATISTICAL DATA OF EARLY AND OF LATE CASES.

It will frequently be necessary to refer to the data which I have obtained from the pathological records of the Middlesex and of Guy's Hospitals for the 30 years 1871–1900. The two records have been kept separate for purposes of comparison, since they are entirely different in character. Owing to the right of patients in the special cancer wards of the Middlesex Hospital to remain until "relieved by art or released by death" a large proportion of the necropsies are on cases which have run their full course. The pressure on the accommodation of Guy's Hospital leaves no room for this class of case in the surgical wards. Hence in the smaller total of necropsies at Guy's Hospital there is a large proportion of cases in the operable stage—of cases which died after operation or from intercurrent disease. Naturally a large majority of these cases occurred in the earlier (pre-antiseptic) portion of the period under review, while, on the other hand, the number of necropsies from the special cancer wards of the Middlesex Hospital has remained practically constant. These two sets of cases will be referred to as the "early" (Guy's) and the "late" (Middlesex) set of cases, though of course some late cases occur in the Guy's records and some early ones in those of the Middlesex Hospital.

ABDOMINAL AND THORACIC INVASION OFTEN INDEPENDENT EVENTS.

Thoracic metastases occur without any invasion of the abdomen in 10 per cent. of the early and in 22 per cent. of the late cases. Conversely, abdominal metastases occur without any invasion of the thorax in 17 per cent. of the early and in 11 per cent. of the late cases. The latter fact especially is a very striking one, to which I cannot too strongly direct your attention. For according to accepted theories the abdomen is always invaded by way of the thorax, whereas it would appear from these figures that, in point of fact, invasion of the abdomen and invasion of the chest are, or may be, entirely distinct events requiring separate consideration. Invasion of the abdomen will be considered first.

THE EARLY STAGES OF ABDOMINAL INVASION.

Cases in which abdominal growth is present only in a single organ or pair of organs are to be regarded not as examples of the haphazard incidence of cancer but as indicating the usual starting points of the attack on the abdominal viscera. When only one organ is affected it may be inferred that the invasion is in an early stage, unless, as is often the case in the liver, the organ is extensively infiltrated. Of the whole number of cases a single abdominal organ or pair of organs was affected in 115—i.e., in 27 per cent. Table III. shows the incidence upon the various organs.

An account of abdominal dissemination must explain not only why the liver is usually the point of first attack but also why the pelvic viscera, and more rarely the portal glands and the peritoneum, may exceptionally present the earliest metastases. The ten cases in which cancer was invading the abdomen retroperitoneally also require explanation. This is evidently a later event than transperitoneal invasion, for it occurs only in the late series of cases.

EPIGASTRIC INVASION OF THE ABDOMEN THROUGH ITS PARIETES.

In the autumn of 1903 I was present at the necropsy on a case of cancer of the breast of which the following is a brief account.

CASE 1. *Epigastric invasion.*—The patient was aged 63 years. Twenty-one months before death the left breast and axillary glands were removed for cancer. Two months before death she was readmitted with numerous subcutaneous nodules in the region of the scar, especially below it, where they extended nearly to the costal margin. Three weeks after readmission a large mass, diagnosed as omental growth, was felt in the abdomen. At the necropsy no glandular or other metastases were found in the thorax, while in the abdomen they were numerous. The left lobe of the liver was riddled by secondary deposits, which in the right lobe were more sparsely distributed. The fat around the pylorus contained numerous cancer nodules. An irregular nodular line of growth ran along the mesenteric attachment of the small intestine. Douglas's pouch was filled by a mass of diffuse growth in which the ovaries lay imbedded. The omentum appeared normal, though one or two cancerous glands were present in it high up. The large abdominal mass which made its appearance just before death proved to be a diffuse cancerous infiltration of the mesentery, apparently spreading from the lumbar glands. None of the retroperitoneal organs were invaded by cancer.

---

[1] A[illegible] n THE LANCET of

TABLE III.—*Derived from 422 cases of Cancer of the Breast, showing in what number of instances, either with or without other metastases, a single* abdominal *organ or pair of organs was affected by cancer.*

	Organ affected.	Guy's cases.	Middlesex cases.	Total number of cases.

* Out of 93 cases = 18 per cent. † Out of 329 cases = 29 per cent.
‡ Out of 422 cases = 27 per cent.

As a preliminary to the consideration of this case the subject of transperitoneal implantation must be briefly dealt with. It seemed quite certain in this case that cancer cells had escaped into the peritoneal cavity and had implanted themselves at various points. Only the organs covered by peritoneum were cancerous. The filling of Douglas's pouch by a diffuse mass of growth matting the pelvic structures, a condition which is recorded four times in 422 necropsies, showed the influence of gravity on the site of implantation. In one case I have been able to trace the earliest stage of pelvic invasion—a case in which the only pelvic deposit was a solitary miliary nodule, microscopically proved to be cancer, on the floor of Douglas's pouch.

Omental cancer.—Cancer of the omentum occurred in only 1 per cent. of the cases of cancer of the breast which I have collected and this is an obvious argument against the view that escape of cancer cells into the peritoneal cavity is a frequent event. The case I have just related throws light on this point. A microscopic section of the apparently normal omentum in Case 1 showed it to be bordered by a false membrane containing degenerate cancer cells. It appears that the pre-eminent encysting power of the omentum usually, though not invariably, enables it to protect itself against invasion and that this fact explains the rarity of omental cancer. The most interesting form of omental cancer is that in which numerous secondary growths hang from the surface of the omentum as cancerous polypi attached by delicate non-cancerous pedicles. In such cases trans-cœlomic (i.e., trans-peritoneal or trans-pleural) implantation is seen in its most unequivocal form. Beneke is stated by Borst to have observed in peritoneal fluid minute spherules of cancer cells surrounded by an organised layer of non-vascular lymph. Often, no doubt, the cancer cells thus encysted are destroyed but sometimes the condition above described results in consequence, as it seems to me, of the adhesion of these encysted masses to the great omentum and of their continued growth. In a later stage the polypoid growths become sessile and invade the substance of the omentum, which is at last seen as a transversely elongated tumour puckered up along the lower border of the transverse colon.

The main problem to be solved in Case 1 may be stated as follows: How, in the absence of invasion of the thorax, did cancer obtain access to the abdomen? The presence of subcutaneous nodules nearly as far down as the left costal margin, and the predominant incidence of cancer upon the left lobe of the liver, suggested to me a direct invasion of the abdominal cavity through the epigastric parietes where the left lobe of the liver lies in direct contact with them. An opportunity of testing this hypothesis presented itself in the next two cases. Though in both these cases the chest as well as the abdomen had been penetrated there was conclusive *direct* evidence of invasion through the abdominal parietes of the epigastric region. It is immaterial to my argument whether in these particular cases the abdomen was also invaded *viâ* the thoracic cavity.

CASE 2. *Epigastric invasion.*—The patient was aged 36 years. Two years before death the right breast was removed for carcinoma. At the necropsy the thoracic wall showed an extensive cancerous ulcer extending inwards to the middle line and outwards to the axilla. Beneath the ulcer the growth had invaded the underlying muscles and pleura. The left pleura and pericardium also showed cancer. The axillary, supraclavicular, and posterior mediastinal glands were cancerous. The only visceral metastases were a large solitary nodule in the liver at the umbilical notch and nodules in both ovaries. In the vicinity of the primary growth were some scattered subcutaneous nodules. The lowest of these was situated eight inches above the umbilicus. It was found that permeation of the deep fascia had extended downwards two and a half inches below this nodule. At the level of the tip of the ensiform cartilage there were nodular deposits on the anterior layer of the rectus sheath. Here the rectus muscle was deeply invaded by growth and a fibrous septum containing permeated lymphatics was traced three millimetres backwards into the substance of the muscle. In order to trace the further course of the growth sections of the falciform ligament and of the included round ligament of the liver were made at different points. (*a*) In a section of the falciform ligament about three inches long, parallel to, and six millimetres distant from, the convex surface of the liver, growth was found about three millimetres from the anterior margin of the ligament. (*b*) In a section near the umbilicus where the parietes had been proved to be free from growth none was found in the round or falciform ligaments. (*c*) In a section of the round ligament just within the umbilical fissure scattered cancer cells could be seen in the subendothelial tissue all round it. (*d*) A section of the falciform ligament taken far back, beneath the diaphragm, was free from growth.

In this case it was demonstrated (*a*) that fascial permeation had extended considerably below the ensiform cartilage; (*b*) that the rectus muscle in the epigastric angle was in consequence deeply invaded by cancer; (*c*) that at the same level there was a large solitary nodule in the contiguous portion of the liver; and (*d*) the escape of cancer cells into the cœlom, their gravitation to its lowest point, and their subsequent implantation, were shown by the nodules in each ovary, which were the only other abdominal metastases. It will be noted that in this case epigastric invasion was apparently subsequent to, though not consequent upon, invasion of the thorax. If this were usually the case the surgical interest of epigastric invasion would be comparatively slight.

CASE 3. *Epigastric invasion.*—The patient, aged 57 years, died from a cancer of the left breast two years after it was first noticed. Ten months before death she became jaundiced and at this time the left breast was represented by a shrunken ulcerated scirrhus puckering the surrounding skin. The reporter notes that there was marked tenderness just below the ensiform cartilage but no obvious enlargement of the liver. A hard lump appeared in the *right* breast just before death. At the necropsy there was cancer *en cuirasse* over the left side of the chest. There was no ulceration of the primary growth at the time of death. It had extended through the chest wall. The pleura and pericardium beneath showed minute nodules and some of the bronchial glands were cancerous. There were no other deposits in the chest. Upon the convex surface of the liver in the neighbourhood of the falciform ligament a few small nodules of cancer were visible but none were present in the substance of the organ. The common bile-duct was surrounded and constricted near its outlet by a nodule of growth. The left kidney showed cancer at one point on its surface. On the pelvic peritoneum were some small flat cancerous nodules. On the parietal peritoneum at the level of the tip of the ensiform cartilage a few miliary nodules were visible. Above and below this point the peritoneum appeared normal. This was especially noted to be the case at the attachment of the diaphragm to the ensiform cartilage.

A vertical section of the entire thickness of the abdominal wall from skin to peritoneum in the subxiphoid region showed the following points: (*a*) the skin was free from growth; (*b*) the deeper part of the subcutaneous fat was extensively infiltrated, while the more superficial layers were comparatively free; (*c*) the deep fascia was much thickened and infiltrated throughout by growth; (*d*) the superficial fibrous bundles of the linea alba were much eroded by growth; lines of cancer cells, apparently lying partially in lymphatic vessels, could be seen passing between its bundles and debouching on the subperitoneal fat (the transversalis fascia is in this situation hardly recognisable as a distinct layer); (*e*) the subperitoneal fat, between whose bundles wide empty interspaces are present, was practically free from growth; though this layer had itself escaped it could offer but a minimum of resistance to the passage of cancer cells through it; and (*f*) the peritoneum showed cancerous permeation of the subendothelial lymphatic plexus; many cancer cells were also lying in the cellular interspaces. Here and there the peritoneal endothelium overlying the cancer cells was degenerate. Quite evidently at these points cancer cells were entering the peritoneal cavity.

In each of three sections taken at different levels through the falciform and round ligaments between the umbilical notch and the anterior abdominal wall a small area of cancerous permeation was found in the falciform ligament. The permeated lymphatics were found only in the *left* lamina, to which (owing to the attachment of the falciform ligament to the posterior layer of the *right* rectus sheath, an inch to the right of the middle line) cancer would first naturally extend from the epigastric peritoneum. The two laminæ of the ligament are here separated by a thick pad of fat. If growth had extended downwards through the diaphragm one would naturally have expected the impartial invasion of *both* laminæ. Moreover, a section of the falciform ligament far back under the diaphragm was found to be free from growth.

The escape of cancer cells into the peritoneum was locally shown in this case merely by a few small macroscopic nodules on the convex surface of the liver. Gravity had carried a few cells into the pelvis where they had given rise to small peritoneal nodules. The permeated lymphatics which were found in the falciform ligament are anatomically known to lead to, or from, the portal gland [illegible] group of metastases, [illegible] round the invaded g[illegible] vicinity. Such appears to be the explanation of the pyloric nodules and of that in the bile-duct. The only remaining abdominal focus was that in the right kidney. (See later—retroperitoneal invasion.)

It appears, then, that of three necropsies, all occurring within the space of three months, presumptive evidence of epigastric invasion just below the ensiform cartilage was obtained in the first one and conclusive evidence in the last two. During this period a total of five necropsies on cancer of the breast might on the average be expected at the two hospitals concerned. The inference that epigastric invasion is a frequent event seems unassailable.

Anatomy of the Epigastric Angle.

It is somewhat remarkable that so far as I can find it has never been suggested, even as an arm-chair hypothesis, that cancer of the breast directly invades the abdomen through the epigastric parietes. Mr. A. M. Sheild, for instance, the most recent systematic writer on cancer of the breast in this country, says:[2] "It seems hardly logical to assume that growths of the ovary, uterus, or liver, occurring perhaps years after an amputation of the mamma, are true recurrences in the strict sense of the word. Their occurrence, however, is very mysterious and significant and at present wrapped in obscurity." And yet the anatomy of the epigastric region strongly suggests the likelihood of this mode of invasion. According to Mr. H. J. Stiles, the lower and inner margin of the breast overlies the sixth costal cartilage—that is to say, this part of the circumference of the breast is distant only about an inch from the interspace between the ensiform and the seventh costal cartilages. Thus as soon as parietal permeation has extended little more than an inch beyond the edge of the breast the cancerous lymphatics of the deep fascia are no longer separated from the subserous (subperitoneal or subpleural) fat by a bony cage of many layers, covered by thick muscles, but simply by a single layer of fibrous tissue, traversed by lymphatic channels. For at the tip of the ensiform cartilage the transversalis fascia is hardly recognisable as a distinct layer and the parietal lymphatic plexus is separated from the subperitoneal fat simply by the linea alba. It is not surprising if, through this obviously weak spot, cancer frequently reaches the peritoneum before it has succeeded in reaching the well-protected pleura, even at points directly subjacent to the primary focus.

A Statistical Study of Epigastric Invasion.

The occurrence of epigastric invasion has now been histologically proved in two cases. It is impossible single-handed to examine a large number of cases by this laborious method. To obtain a broad view of the subject it is necessary to turn to post-mortem records. In the absence of direct evidence for any other hypothesis it is legitimate to assume epigastric invasion in all cases in which the thorax has escaped invasion and in which at the same time metastases are present in the viscera intimately related to the peritoneum. Excluding six cases in which co-existent bone or brain metastases might *primâ facie* indicate embolic blood invasion no fewer than 53 such cases were found among 422 necr[illegible] the group is a natural one th[illegible] ses is practically identical [illegible] of cases. It must be emphatically stated that these cases do not represent the whole number in which epigastric invasion occurs, for all cases in which previous or subsequent invasion of the thorax took place are *ipso facto* excluded from consideration.

It appears, then, that at the time of death *uncomplicated* epigastric invasion, apart from the independent invasion of the thorax which must often precede or follow it, is present in 12 per cent. of all cases. The total incidence of epigastric invasion must be somewhere between 12 per cent. and 46 per cent., the difference between these figures representing the percentage of (late) cases in which both the chest and the abdomen are invaded. Probably the latter figure is much nearer to the truth than the former one.

Epigastric Invasion an Early Event.

It is of great practical importance to know whether epigastric invasion usually takes place before or after invasion of the chest. If it is an early event invasion of the abdomen may be found apart from invasion of the chest more frequently in the early than in the late set of cases.

Table IV.—*Showing the Comparative Invasion-percentages of the Thorax and Abdomen in an Early (Guy's) and a Late (Middlesex) Set of Cases.*

—	Early cases	Late cases.
	Per cent.	Per cent.
Metastases present in the abdomen and not in the thorax (abdominal group)	17	11
Metastases in the thorax and not in the abdomen (thoracic group)	10	22
Metastases in both cavities (abdomino-thoracic group)	20	35
No metastases present	40	23
Other cases, e g., those of bone invasion ...	13	9

The early cases, as might be expected, are more often free from metastases and less frequently show thoracic or abdomino-thoracic invasion. On the other hand, there is this apparently anomalous fact—that the early series shows, as compared with the late series, a considerably *larger*

---

[2] Sheild Diseases of the Breast, 1898, p. 457.

In three of these 11 cases the adherent pleura on the side of the growth had escaped invasion, while the opposite non-adherent pleura was cancerous.

Doubt may at first sight appear to be thrown on this evidence of the protective action of an adherent pleura by the fact that only 30 per cent. of the cases with pleural adhesions were absolutely free from metastases, as compared with 33 per cent. of the sum-total of cases—an inappreciable difference. But the protective action of an adherent pleura extends only to thoracic metastases. It has been shown that in a large proportion of cases invasion of the abdomen occurs not by way of the thorax but directly through the epigastric parietes. Pleural adhesions do not check this process; perhaps, indeed, their resistance to the deep extension of the growth may accelerate the progress of fascial permeation and so actually favour epigastric invasion. It is a most striking fact that while only 12 per cent. of a total of 329 cases showed the abdomen invaded by cancer and the chest free, 32 per cent. of the 37 cases with marked pleural adhesions showed invasion of the abdomen coexistent with freedom of the thorax from secondary deposits. The converse difference is equally striking. While 22 per cent. of the Middlesex Hospital necropsies show the thoracic cavity invaded and the abdomen free, only 5 per cent. of the cases with pleural adhesions show a similar state of affairs. These facts are a strong indirect testimony both to the protective influence of pleural obliteration and to the frequency of direct epigastric invasion of the abdomen. It is difficult to see how the embolic theory of dissemination can be made to explain them. The possibility of delaying dissemination and of prolonging life by artificially producing obliteration of the pleural cavity is one not to be entirely lost sight of.

DISSEMINATION IN OTHER FORMS OF CARCINOMA.

That permeation is the main factor in dissemination has been proved for some of the few cases of cancer of the breast I have been able to investigate. Outside these cases, for cancer of the breast in general, I have attempted to show that the permeation hypothesis of dissemination agrees with, and is the best explanation of, the peculiarities of metastatic distribution as seen in post-mortem records. If the permeation hypothesis can account for the widely scattered metastases of cancer of the breast it seems *a fortiori* the most likely explanation of the less extensive dissemination seen in most other forms of carcinoma. The distribution of the metastases, which for each form of carcinoma is variable and characteristic, appears to depend chiefly on the lymphatic relations of the primarily cancerous organ. The metastases of cancer of the breast are especially numerous and widespread, partly because of the intimate relations of the breast and the extensive fascial plexus, but also because the breast is favourably situated for the invasion either of the thorax or of the abdomen. The latter cavity, too, is invaded at its summit, whence showers of cancer cells are distributed by gravity over all the organs in relation to the peritoneum.

PRACTICAL CONCLUSIONS.

These must be very briefly stated.[5] If, when it transgresses the limits of the breast, cancer spreads primarily in the deep fascia the main operative aim next, of course, to complete removal of the breast and of the axillary glands, should be the removal of as wide an area as possible of the deep fascia. And if the mode of fascial extension is by centrifugal continuous permeation, the area affected is roughly a circle and the area of fascia removed should also be circular with its centre at the point of origin of the primary neoplasm. The use of the expression "pectoral fascia" to describe the area which requires removal and the almost exclusive attention paid to the axillary glands as the channels of dissemination have led to inadequate excision of the deep fascia in a downward direction over the upper part of the abdomen. In order to prevent epigastric invasion the usual incision should be prolonged downwards over the linea alba for about two inches, the flaps undermined, and the fascia excised as far down as a horizontal line running two inches below the ensiform cartilage, or even lower if the growth is in the inferior part of the breast. I have not found that this step increases the shock of the operation. Excision of the overlying skin and of the underlying muscle must be free but need not be carried out over so wide an area as excision of the fascia, for the extension of the growth to skin and muscle is a secondary process.

Removal of the deep fascia appears to be carried out more thoroughly in this country than elsewhere. In America Halsted, whose valuable work on surgery of the breast is so widely known and appreciated, lays stress rather on the removal of a wide area of skin. To this extent the English operation seems based on sounder pathological principles. At the Middlesex Hospital especially, whence came the first protest by Moore,[6] which was vigorously supported by Campbell de Morgan, and by Nunn, and others of the past and present staff, against the incomplete operations formerly in vogue, excision of the deep fascia is at the present day carried further than has to my knowledge been publicly advocated by any English surgeon, though among others both Jacobson and Watson Cheyne advise very wide excision of this layer. It appears to me, however, that even the widest removal of deep fascia as at present carried out is deficient in the direction of the epigastrium. Owing to the fact that the abdominal muscles arise well above the costal margin, the excision of the deep fascia over the origins of these muscles, a step which forms part of the accepted operation, does not necessarily involve any interference whatever with the epigastric deep fascia, still less such an extensive removal of it as I am at present advocating.

Local and intrathoracic recurrence after the operation for cancer of the breast appears to take place more and more rarely in the practice of experienced surgeons—that is to say, the modern operation seems to afford a maximum of protection so far as the chest is concerned. On the contrary, it appears from statistical records that the operation for cancer of the breast as at present usually performed does not by any means give the maximum attainable security against *abdominal* recurrence. For while modern results show a diminution in the sum-total of cases of recurrence cases of purely abdominal recurrence seem to be increasing in frequency relatively to the lessened number of thoracic recurrences. And this phenomenon is clearly seen only in the results of the more successful operators—i.e., of those whose methods enable them to guard against thoracic invasion.

Only last week I had the opportunity of seeing a patient whose right breast was removed for cancer 28 months ago by a surgeon of large experience in the surgery of the breast. Subsequently the disease recurred in the opposite breast which was removed by another surgeon. Even at the time the second breast was removed the patient was beginning to suffer from pain in the left ovarian region. At the present time there is no local recurrence but the pelvis is filled by cancerous masses and per vaginam an ulcerated growth can be felt indistinguishable from a primary carcinoma of the cervix. The mammary operation scars reach downwards only to a point two inches above the tip of the ensiform cartilage and it therefore seems unlikely, even allowing for their contraction, that the deep fascia of the epigastric region was removed at the time of operation. It is my opinion that in this case the pelvic mass of growth resulted from epigastric invasion and was not a second primary carcinoma. During the past few weeks I have heard, through Mr. C. J. Symonds and Sir Alfred Fripp, of three other cases of exclusively abdominal recurrence, in one of which palpable subcutaneous nodules were present in the epigastric region.

The relative excess of abdominal recurrences associated with modern methods of operation is strikingly exhibited in the cases, upwards of 100 in number, published by Professor Watson Cheyne. Visceral recurrence took place in 15 cases. In ten of these cases the recurrence was (clinically) abdominal, while in only five was it (clinically) thoracic. It seems to me almost certain that in some of these cases abdominal recurrence might have been prevented by a wider excision of the deep fascia in the epigastric region. I will therefore conclude by expressing the hope and, indeed, the firm belief, that a recognition of the danger of epigastric invasion and the adoption of precise means for its prevention will bring about a further appreciable reduction in the mortality from mammary carcinoma.

The Goulstonian Lectures

ON

SOME CONSIDERATIONS ON THE NATURE OF DIABETES MELLITUS.

Delivered before the Royal College of Physicians of London on March 16th, 21st, and 23rd, 1905,

BY W. CECIL BOSANQUET, M.A., M.D. OXON., F.R.C.P. LOND.,

ASSISTANT PHYSICIAN TO CHARING CROSS HOSPITAL AND TO THE BROMPTON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST; FORMERLY FELLOW OF NEW COLLEGE, OXFORD.

LECTURE III.[1]

Delivered on March 23rd.

MR. PRESIDENT AND GENTLEMEN,—In my first lecture I ventured to suggest that the essential nature of diabetes mellitus, as opposed to mere symptomatic glycosuria, consisted in an internal formation of sugar from the tissues of the body, while the liver had nothing to do with this condition, being responsible only for a possible aggravation of the existing symptoms by temporary increase of the sugar existing in the blood and thence appearing in the urine. In my second lecture I pointed out some of the reasons which exist for believing that defect in the pancreas is responsible for diabetes. I also mentioned that suggestions had been made with regard to a possible interaction between the pancreas and other organs in the process of regulating the formation and destruction of sugar and dealt with the question of the alleged action of the liver in this respect. Two other organs must also be alluded to as suggested partners with the pancreas—the suprarenal body and the thyroid gland.

The suprarenal body.—The hypothesis of a joint action of this gland with the pancreas is supported by definite experimental evidence and a special form of diabetes, the *Nebennierendiabetes* of the Germans, has been supposed to exist. Experiments show that the injection of suprarenal extract is followed by the appearance of sugar in the urine and the condition is seemingly very similar to true diabetes. The sugar may appear in the urine even when the animal receives only a proteid diet. Feeding by the mouth with suprarenal extract does not produce glycosuria, and subcutaneous injection of it is less efficacious than intraperitoneal. Croftan has called attention to the pigmentation of the skin which occurs in hæmochromatosis as well as in Addison's disease, and has used this resemblance as an argument in favour of a connexion between the suprarenal body and diabetes. Since, however, glycosuria does not usually occur in Addison's disease it is clear that it is not defect in the function of the suprarenals which leads to glycosuria, whereas it is with such defect that pigmentation seems to be connected; hence the argument does not seem valid. On the other hand, an excessive action of the suprarenal might conceivably be responsible for diabetes as [illegible] cretion of these glands when [illegible] act upon the pancreas and to [illegible] Thus, it is found that painting the extract upon the pancreas is followed by an excretion of sugar, whereas similar application to the liver or spleen is not productive of the same result. Curiously enough, the surface of the pancreas when thus treated is stated to become pink and hyperæmic instead of blanched, as is the case with other parts which are similarly treated. The property of inducing glycosuria when applied to the pancreas is not, however, confined to suprarenal extract but is exhibited by other reducing agents, such as sulphurous acid, ammonium sulphide, coal-gas, carbonic oxide, &c., so that it is to the reducing action of the suprarenal secretion and not to any specific effect that the appearance of the glycosuria is to be attributed. It is, indeed, said that in fatal cases of poisoning by an overdose of suprarenal extract the cells of the islands of Langerhans are the seat of granular degeneration, while the other cells of the pancreas are not equally affected, but this statement needs confirmation. In any case, the peculiar effect of the secretion of the suprarenal body in producing glycosuria must be attributed to its action on the internal secretion of the pancreas, and there is no evidence that in spontaneous disease any overaction of these bodies takes place or that they are in any way connected with the origin of diabetes mellitus.

The last organ which has been supposed to exert a joint action with the pancreas in destruction of sugar is the *thyroid gland.* Its claims have been urged recently by Lorand of Carlsbad in a lengthy monograph on the production of diabetes This writer states that in diabetic patients the thyroid is often markedly enlarged—a condition which is not, so far as I know, generally noted in text-books as a symptom of the disease and which I have not personally observed in these cases. He further points to the frequent presence of sugar in the urine of patients suffering from Graves's disease; to the onset of this condition as a result of fright or mental stress—factors which may act as causes of diabetes; and to the sweating which some diabetics exhibit, resembling the sweats so common in Graves's disease, which also may be accompanied by pruritus, pigmentation of the skin, and psychical phenomena. All the symptoms of diabetes can be induced, according to Lorand, by administration of excess of thyroid extract. He considers that the thyroid, the pituitary body, the suprarenal bodies, and possibly the testes and ovaries are all vascular glands (*Blutgefassdrusen*) and that the islands of Langerhans in the pancreas are also to be placed in this class. All these structures are correlated in function, and defect of one of them produces alterations in the others. Thus in cases of Addison's disease the pancreas is often, he affirms, large and hyperæmic, while the thyroid is small and atrophic. He thus brings myxœdema and Graves's disease, acromegaly, Addison's disease, and diabetes into one group of disorders depending upon alterations in the vascular glands—a sufficiently heterogeneous collection, though perhaps hardly equal to that embracing gout and rheumatism, epilepsy, Raynaud's disease, megrim, hysteria, Bright's disease, chlorosis, and diabetes itself, seriously maintained by one of the Fellows of this College to be all due to poisoning with uric acid introduced with the food (Haig). Lorand states that it is chiefly in female diabetics that actual enlargement of the thyroid is present though why the other sex should not also exhibit the same alteration is not clear. He further says that post mortem the gland is soft and that the amount of colloid substance present in it is increased. He quotes some other writers who have found changes in the gland; thus, Rosenfeld noted them in three cases out of 15, while Bachstein and von Noorden record the existence of enlargement in different proportions of their cases. Some support, perhaps, is lent to Lorand's views by the experiments of Knopfelmacher, who examined the alimentary capacity in regard to assimilation of sugar in two patients suffering from congenital myxœdema; he found that the assimilative power for sugar was much greater in these cases than in normal persons Lorand also claims to have obtained good results in the treatment of diabetes by the use of milk derived from animals which had undergone thyroidectomy. It would thus seem that the presence of sugar in the urine may in some cases be connected with an over-activity of the thyroid gland. There does not seem to be sufficient evidence that this organ is at fault in true diabetes. In a case which I recently examined the thyroid gland appeared quite normal both in size and structure I also remember reading an account of a case in which diabetes coexisted with myxœdema though I cannot put my hand upon the reference. It is, however, desirable to pay careful attention to the condition of these vascular glands in necropsies upon diabetic cases in order to ascertain the frequency with which pathological changes occur in these parts.

PATHOGENY.

I have now to consider some of the views which have been held as to the pathogeny of the disease—the actual mode of production of the defect in metabolism which constitutes diabetes—and to bring before you any facts which appear capable of throwing light upon the difficult problems involved. In the first place, if we ask in what way the pancreas exercises an influence upon the production or assimilation of sugar, it must be confessed that its mode of action is not by any means clear. Two ai were originally suggested by von Mering and Minkowski: (1) that the pancreas forms an internal secretion necessary for the regulation of the sugar-forming and destroying activities of the organism; and (2) that it may neutralise some poisonous material formed elsewhere, which acts injuriously upon these processes. The authors just named discarded the latter theory and adhered to the former. The pancreas would thus come into the same category as the thyroid gland, the existence of an internal secretion from which is now definitely established, and with the ovaries, testes, suprarenal bodies, pituitary body, and thymus in the case of which an internal secretion remains hypothetical, possessing varying degrees of probability in the cases of the different organs mentioned. It may be remarked that it is not the fact of the existence of an internal secretion in these cases which is questionable, for every organ and tissue in the body must in one sense form an internal secretion, inasmuch as it casts off into the circulation substances formed in its life processes—waste products in fact. The question is as to the usefulness of the materials thus formed to other parts of the body. In the case of the thyroid the useful character of its secretion has been most conclusively demonstrated by the results of feeding myxœdematous patients with the substance of the gland. Unfortunately this proof does not exist in the case of any of the other glands in question—possibly because the digestive juices destroy the substances manufactured by them. In the case of the pancreas an instance is, indeed, reported by Wegele in which the use of pancreatic extract caused cessation of glycosuria in a case of apparent diabetes with fatty stools. It is interesting to note that in this instance alimentary glycosuria remained after the treatment, a fact which may afford some support to the view which I have suggested that alimentary glycosuria and diabetes are in many cases quite independent processes. It is held by most authorities that in cases of mere alimentary glycosuria no alteration can be made out in the pancreas (Wille).

---

[1] Lectures I. and II. were published in THE LANCET of April 8th (p. 903) and 15th, 1905 (p. 977), respectively.

Now, in endeavouring to elucidate the possible action of the pancreas upon metabolic processes it is natural to seek to associate it with views recently set forth as a result of study in quite a different field of pathology—namely, that of infection and immunity. The whole subject of immunity was exhaustively discussed two years ago by Grünbaum in his Goulstonian lectures and I need not do more than allude to the salient points which bear upon my present subject. In the first place it is found that when bacteria enter the circulation, or when blood corpuscles from one species of animal are injected into one of another species, these intruders are destroyed by the interaction of two distinct bodies, one of which—the alexine or complement—exists naturally in the serum of normal animals, while the other—the copula or immune body—is formed in response to the stimulus of the injected foreign material. The use of the second body seems to be to unite the alexine to the intruding bacterium or corpuscle and thus enable it to destroy the latter.

We are here introduced to chemical actions of great complexity in which three or more bodies take part, as contrasted with the simpler reactions of non-vital chemistry in which two bodies are generally concerned. We may compare with the processes sketched above that of the coagulation of the blood, in which it has long been known that three or more substances take part—the fibrinogen, the fibrin-ferment and calcium salts; or the action of the digestive ferments, pepsin and trypsin, in the presence of acids and alkalies respectively; or the curious interaction between pancreatic secretion and intestinal juice, in which the inert protrypsin is rendered active by enterokinase. One is tempted to speculate whether we may here be in the presence of a general law of vital chemistry, by which a complicated reaction between three or more bodies—one of which is generally a ferment—is substituted for the simpler interchanges in non living materials.

Further, in studying the formation of antitoxins Professor Ehrlich was led to formulate his well-known hypothesis of side-chains or receptors. According to this living cells consist of a central mass of protoplasm to which are attached outlying groups of molecules (side-chains or receptors) having the property of entering into combination with bacterial toxins. Now, since it would obviously be better for an organism to possess no receptors capable of uniting with toxic molecules we cannot suppose that the side-chains exist for the purpose of combining with these. It is therefore held that they are primarily intended for the assimilation of food molecules and are only accidentally capable of uniting with toxins. It thus seems possible that the assimilation of sugar by the tissues is carried on by some process allied to the union with toxins. The phenomena of diabetes may thus some day be brought into line with these observations in one of several ways.

1. In the first place, a view very commonly held is that the disease consists in a defective power of assimilating sugar, the defect residing in the tissues throughout the body. It would appear at first sight tempting to suppose that the connexion of the pancreas with diabetes lay in the formation by it of some copula by which molecules of sugar are anchored to the cells; if this be not supplied the assimilation of sugar will then be no longer possible. An analogous defect might be supposed to exist in myxœdema, the thyroid gland here failing to supply an intermediary substance necessary for the utilisation of some other form of cellular pabulum. I do not, however, think that this is the true explanation for more than one reason. In the first place there does not seem to be any convincing evidence that such failure in the assimilation of sugar by the tissues actually exists. The presence of fat-droplets in the muscles and elsewhere may indeed be pointed to as evidence of lack of normal assimilative powers but it can be otherwise explained. Secondly, as I previously suggested, it seems certain that in the terminal stages of diabetes sugar is formed from the tissue cells and it seems preferable to apply this explanation of the excess of sugar present in the blood to the whole course of the disease. Defect in the formation of an intermediary body would not explain this phenomenon.

2. We may, however, consider in this connexion the hypothesis advanced by Lépine, who explains the phenomena of diabetes by the absence from the blood of a sugar-splitting ferment which it normally contains. He finds that healthy blood possesses the power of causing the disappearance of a certain amount of the contained sugar when it is allowed to stand. Diabetic blood, on the other hand, possesses this property to a notably less degree according to this observer. Croftan has supported Lépine's observations of a power of destroying sugar resident in the blood and lymph. He states that the glycolytic power of the blood is diminished after removal of the pancreas. He also claims to have isolated the ferment by which this action is performed and to have identified it with trypsin. He finds that in the presence of hæmoglobin trypsin has the power of destroying sugar, but apart from the former the normal pancreatic juice has not this property. The glycolytic ferment of these writers would be analogous presumably to an alexine rather than to a copula. Croftan considers that it is formed by the pancreas. Other observers have, however, pointed out that the glycolytic power of the blood increases after it has coagulated, thus appearing to be a non-vital phenomenon, while the process depends to a considerable extent upon the amount of water present in the blood (Biernacki), so that the failure of diabetic blood to destroy sugar may be dependent upon its concentration. Umber found that the glycolytic power of the blood was not increased in the pancreatic vein, as it would have been had the pancreas formed the destructive body. With regard to the glycolytic power of the tissues Giacco found that it varied in different organs, being great in the heart and little in the pancreas. He also found that it remained after boiling the tissue and so was not a vital action. It is interesting to note, in view of the acid poisoning which exists in diabetes, that according to this observer alkalies increase the glycolytic property while acids diminish it.

3. If the action of the pancreas, then, is not in the direction of assisting in the utilisation of sugar, there remains the suggestion that it in some way neutralises or destroys a poison which either interferes with some part of the process by which sugar is assimilated or increases the formation of sugar within the body. This the pancreas might do by absorbing the poison and using it for its own metabolic processes, or by forming an antitoxin which would meet and neutralise the toxin in the blood. In the latter case we should again be in presence of a phenomenon analogous to those supposed to occur in bacteriolysis and immunity. Once more it must be confessed that the evidence in favour of a toxic origin for diabetes is hopelessly scanty; yet there are a few indications pointing that way, and in the state of darkness which prevails as to the pathology of this disease the smallest ray of light is better than none. In the first place we have the undoubted fact that experimentally

certain poisons are capable of producing a condition closely resembling diabetes—indeed, as far as we can see, identical with it. The most notable instance—that of phloridzin poisoning—has already been referred to, but other substances, such as diuretin and uranium nitrate, may also produce at least glycosuria, while the effect of suprarenal extract and other reducing substances applied to the pancreas has just been mentioned.

With regard to the actual presence of poisons in diabetes very little direct evidence has been brought forward. Klemperer was apparently the first to suggest that there was present in the disease a poison which interferes with the oxidation of sugar. This hypothesis has been revived by Leo. Long ago Minkowski made experiments to investigate the matter by injecting the blood of a dog rendered diabetic by removal of the pancreas into a normal dog, but the result was negative and indeed was so almost of necessity, since even if the blood of the diabetic dog contained a poison which ought to have been neutralised by its pancreas, yet the normal dog possessed a pancreas capable of dealing with the poison. Lépine injected guinea-pigs with a watery solution of the blood of a diabetic dog and produced a glycosuria lasting for some days, whereas a similar experiment with the blood of a normal dog produced only a very transitory appearance of sugar. From this he concluded that the diabetic organism contains special leucomaines or toxins of internal manufacture. On the other hand, injections of blood derived from pneumonic patients seemed to have a similar power of inducing glycosuria, so that the value of the experiment does not seem very high. Further, the injection of pancreatic emulsion or extract does not seem to influence the condition of animals who have suffered experimental pancreatectomy. The attempt to associate diabetes with an infective micro-organism has—one might say, of course—been made. Topfer and Freund injected animals with the contents of the intestines of diabetic patients and thereby produced a lasting glycosuria; and Hammerschlag and Kauffmann obtained bacteria from the intestines of diabetics and produced a similar result by feeding experiments and by intravenous injections of the organisms. These experiments are not very convincing. It is easy to set up glycosuria in animals in many different ways and there does not seem to be evidence in any of the experiments that a condition analogous to diabetes mellitus was produced. As previously mentioned, there is little evidence that in man diabetes is an infectious malady; even Hutinet, who maintains the possibility of infection, believes that diabetes is a secondary result dependent upon the production of arterio-sclerosis.

On the whole, then, while there is reason to suspect that diabetes may be due to the action of some toxic substance formed within the body, which is normally neutralised or destroyed by the pancreas, nothing approaching to proof of such a substance or such a condition has so far been established.

Acid intoxication.—There remain to be considered one or two sides of the question of diabetes which may throw light upon the nature of the process. The first of these is the so-called acid intoxication which forms so characteristic a feature of the graver cases of the malady. In this condition the alkalinity of the blood is diminished owing to the formation in the system of acid substances which combine with the alkali present in the body fluids. Coincidently, and apparently as a result of the increase of organic acids present, there is given off some excess of ammonia which combines with these and is excreted in this combination in the urine. An increased amount of ammonia in the urine is thus characteristic of acid intoxication. The acids formed appear to be chiefly oxybutyric, amido-butyric, aceto acetic, and others perhaps belonging to the same series, which is intimately connected with the volatile substance, acetone, which gives the sweet smell to the breath of diabetic patients. Acetone is said to occur normally in the urine in minute quantities, too small to be recognised by ordinary clinical tests; but in diabetes it is much increased, and almost as much may be eliminated by the lungs as by the urine. It is accompanied in the latter fluid by aceto-acetic acid which gives the characteristic red colour with perchloride of iron. Acid intoxication may occur in other conditions besides diabetes, though it is most profound in this disease. Thus a certain degree is seen in the summer diarrhœa of children, in starvation, and in many fevers. Acetone is also increased in the urine after the administration of ether and chloroform. In all of these conditions, however, it seems to be a feature of no clinical importance; in diabetes it is of very grave urgency, being the forerunner of the fatal coma which terminates so many cases.

An alkaline reaction appears absolutely necessary for the existence of vital activities in the tissues and grave disturbances of nutrition soon occur if an animal is caused to lose alkali which cannot be replaced from the food. Bunge considered that the toxic substance which accumulates in the body in such cases of withdrawal of alkalies is sulphuric acid. The condition would thus be equivalent to sulphuric acid poisoning. If acids in excess are administered to animals respiration increases in frequency and the pulse-rate rises. Finally, ataxy and convulsions occur and the animal dies in coma. It seems that carnivorous animals are more tolerant of acids than are the herbivora, apparently owing to the greater amount of ammonia which they are capable of forming from their proteid diet. Mankind are capable of dealing with a large quantity of acid in this way.

Excess of acid may occur in the system in two ways: either by failure to excrete that which is normally formed, with resulting accumulation in the blood; or by increased manufacture of acid by chemical processes within the tissues. With regard to the former possibility it is conceivable that lesions of the kidney may at times cause accumulation of toxic substances in cases of diabetes and may thus sometimes precipitate the onset of coma. I alluded in my first lecture to the intense degeneration of the renal tubules which I found in a recent case which died comatose. The sudden onset of coma in some instances could be better understood on such a hypothesis than on that of the gradual accumulation of acids by increased manufacture alone. But such renal lesions are not the invariable rule. In any case the presence of acids appears to be due to formation by the tissues. [illegible] formed i [illegible] oxalic, ur [illegible] which are most to the fore in diabetes—β-oxybutyric and aceto-acetic (diacetic), related to each other and to acetone.

Coma.—The interest of the series of bodies just alluded to—the acetone series—in diabetes is very great, since it is to one or more of them that attempts have been recently made to assign the causation of diabetic coma. Two older theories may be mentioned as of historical interest. One is that coma is due to a fat embolism of the lungs, arising from the presence of excess of fat in the blood in cases of diabetes. This hypothesis seems untenable for more than one reason. In the first place, liphæmia is not by any means of constant occurrence in diabetes and is not found in all or nearly all cases dying from coma; while it is very doubtful whether fat circulating in the blood in the form of fine droplets, as it does in such conditions, is capable of producing embolism of even capillary vessels, since fat is practically fluid at the temperature of the body and is probably thus able to pass through any vessels to which it is conveyed. The existence of fat-globules in the capillaries of the lungs can, it is true, be demonstrated in some instances; but this is after death when the fat has solidified. There is no proof that the fat has been previously arrested in the capillaries and has thus blocked them. It is not impossible that the lungs may act as the mechanism [illegible] excess of fat from the blood, a [illegible] place within them The second [illegible] be made is that diabetic coma is due to accumulation of carbon dioxide in the blood owing to insufficient absorption of oxygen; coma would thus be a form of asphyxia. This view seems negatived by the experiments which have been performed to ascertain the respiratory exchange in diabetics. Recently Pembrey, Beddard, and Spriggs have investigated this in cases of diabetic coma and have satisfactorily shown that defective respiratory exchange can be eliminated as a cause of the condition.

To return to the acetone bodies, the first attempt to connect these with diabetic coma was in the direction of identifying acetone with the toxic body at work. This view was sustained by von Jacksch and others. Experimental injection of considerable amounts of acetone into animals and inhalation of this substance gave rise to a condition of stupor and sometimes to glycosuria. On the other hand, acetone can be given in large quantities by the mouth without giving rise to any ill-effects; and subsequent observers repeating the experiments and studying the production of acetone normally in the body were led to attach little importance to the production of acetonæmia as the cause of coma. Attention was next turned to β-oxybutyric acid as a possible cause, but in the case of this substance also it was found that it could be taken in large amounts without the production of injurious effects; and that it was tolerated even by animals which had been deprived of their pancreases. Such ill consequences as ever ensue after its administration are now assigned to its acid qualities alone, whereby it withdraws a certain quantity of ammonia from the body to neutralise it (von Noorden). Other authors have laid stress upon the presence in diabetic coma of other acids, especially β-amido-butyric acid; but it is now generally held that there is no reason to associate any one substance with this condition, which appears to be dependent upon the general fall in the alkalinity of the blood.

Source of acetone bodies.—Now in view of the importance of the acid intoxication which is present in severe cases of diabetes it is necessary to inquire as to the source of the substance by which it is produced. Since aceto-acetic acid and oxybutyric acid are apparently intermediate products which in normal circumstances are excreted as acetone inquiry may conveniently be directed to ascertain the source of this last. In the first place, experimental investigation has shown that the addition of butter to the diet leads to an increased excretion of acetone, so that it would seem likely that it is a product of the disintegration of fat, which is supposed to enter the system practically unchanged by digestive processes. Consumption of other fats may have a similar effect to that produced by butter. In the second place, the chemical composition of the acetone bodies forcibly suggests an origin from fat, since oxybutyric acid ingested may be excreted as acetone and the relationship of this acid to fat (butter) is sufficiently indicated by its name. A consideration of the chemical formulæ of the substances involved will make the relationship clearer. Glyceryl tributyrate, a typical fat, may be represented as—

$$C_3H_5 \,.\, (CH_3 - CH_2 - CH_2 - CO_2)_3.$$

The figures in the brackets represent the formula of butyric acid—

$$H \,.\, (CH_3 - CH_2 - CH_2 - CO_2).$$

By substituting in this formula OH for one of the atoms of hydrogen we obtain β-oxybutyric acid—

$$H \,.\, (CH_3 - CHOH - CH_2 - CO_2).$$

By combination of the two atoms of hydrogen in the second group with one of oxygen aceto-acetic acid and a molecule of water are formed—

$$H \,.\, (CH_3 - CO - CH_2 - CO_2) + H_2O\,;$$

and by the removal of the last group (CO_2) from this we obtain acetone,

$$CH_3 - CO - CH_3.$$

It would appear, further, that the acetone bodies are formed within the system, not in the intestinal canal, for although small quantities of both acetone and oxybutyric acid have been demonstrated in the contents of the stomach and intestines the administration of purgatives which rapidly clear out the intestinal contents does not diminish the quantity of acetone in the urine; indeed, von Noorden states that it may occasionally even increase it. The acetonuria which occurs in pregnant women is attributed by Stumpf and Stolz to the increased destruction of fat which takes place in the maternal organism and that which sometimes accompanies death of the fœtus has been supposed by Waldvogel to be caused by destruction of fat resulting from the action of toxins absorbed from the uterus. In the absence of evidence to the contrary, then, we are justified in believing that the acetone series of substances is produced within the body from fat. This conclusion appears consistent with the conditions present in the various pathological states in which acetone and its congeners are found to be increased. Thus they are excreted in greatly increased amount in states of starvation in which there is great wasting of the body and in which it has been shown by experiment that the tissue which suffers the most severely is the adipose. A similar explanation would seem to apply to the acetonuria of fevers, of diarrhœal conditions, and of advanced carcinoma, in all of which the fat is suffering serious reduction in quantity. Acetonuria is also seen sometimes as a result of the administration of anæsthetics. Now the two substances most frequently used for narcosis are ether and chloroform, and both of these are capable of dissolving fat outside the body; it is only reasonable to suppose that when they are absorbed into the system they may also be capable of acting upon the adipose tissues.

It is true that von Noorden and Mohr deny the possibility of the acetone bodies formed in diabetes resulting from destruction of fat, although they admit that such destruction commonly takes place in this disease. "This factor," they say, "could only explain the excretion of moderate quantities of acetone not the enormous quantities of acetone bodies that severe cases of diabetes frequently eliminate." They do not, however, support this assertion by any evidence and it is not easy to see on what grounds it is founded, since the quantity of fat that is undergoing destruction at any moment in a case of diabetes must, in the present state of our ignorance, be entirely conjectural. The whole of the argument as set forth by von Noorden and Mohr supports the derivation of the acetone bodies from fat, and it is clear that they are formed within the body, not in the alimentary canal. It may be admitted that the acetone could not all be formed from fat used as food; but there is nothing to show that it is not formed from the fat in the tissues.

Von Noorden attributes the presence of increased acetone in the urine to diminution in the amount of carbohydrate matter in the diet and quotes actual cases in which a great diminution of the acidosis occurred as a result of adding some carbohydrate to the restricted diet of diabetic patients. This is in accordance with the tendency of the present time in the treatment of diabetes not to put patients on so severely restricted a diet as in days gone by; and there seems no doubt that this procedure constitutes a definite advance; while the sudden cutting off of carbohydrates from a diabetic's diet has almost certainly before now resulted in the onset of coma. But, on the other hand, all physicians must be acquainted with cases which have exhibited acetonuria when they first came under treatment but which lost this symptom as a sequel of being put upon a more restricted diet (cf. Herter). It seems not impossible that such concomitant conditions as rest in bed may have some influence upon this phenomenon. Von Noorden himself admits that in diabetes the excreted acetone may suddenly decrease and then increase again without reference to the amount of carbohydrate food taken. At the same time it is quite in accord with the theoretical possibilities that defect in carbohydrate food should lead to some increased destruction of the fat in the body, to make up for the loss of a material which is not only important as a source of energy but is probably itself capable of being stored up—if not actually absorbed as Pavy maintains to be usually the case—in the form of fat.

Source of sugar.—Lastly, we have to consider the question of the source of sugar in diabetes. With regard to this question, attention had been chiefly directed to the possibility of the formation of this substance from the different categories of food materials. Thus it seems to have been satisfactorily established that sugar is excreted whether carbohydrate is given or proteid or fat is substituted. From this it is concluded that sugar is formed by the diabetic organism from all these kinds of food. I venture to suggest that to allege these experiments as a proof that all these materials are capable of being converted into sugar is to be guilty of the fallacy of proving too much. Is it not more probable that what is actually occurring is that the diabetic organism is continually forming sugar out of some of its own tissues, and continues to do so whatever kind of food is administered, than that by some extraordinary perversion of chemical change all these diverse materials are converted into sugar? We ought at all events to consider the more simple explanation very carefully before we reject it in order to adopt the more difficult, especially in the presence of the fact upon which I have already insisted to a degree which I fear may become tedious, that in the final stages of diabetes this internal formation of sugar is admitted to occur.

If we inquire what are the tissues which break down into sugar under these conditions the answer is not easy. It is generally assumed that it is the proteid or protoplasmic substance of the body, in view of the fact that the nitrogen excreted in the urine is increased and that this increase is to some extent proportional to the amount of sugar. Recently Baer has published some observations upon the subject, based on experiments made upon dogs poisoned with phloridzin, showing that the quantities of sugar, of acetone, and of nitrogen excreted, if graphically represented, follow very similar curves. Seeing, however, that the acetone is in all probability formed from fat, not from proteids, and yet follows a curve similar to that of the nitrogenous excretion we *have no right to conclude on this ground that* the source of the sugar is the proteid of the body The increased excretion of nitrogen may be connected with the breaking down of proteid as a consequence of the acid intoxication

Mandel and Lusk also maintain that sugar is derived from proteid finding in a case which they studied a constant ratio of dextrose to nitrogen in the urine On the other hand, Lépine states that diabetics may excrete more sugar than is accountable for either by their diet or by destruction of their proteid tissues and concludes that some of the sugar is formed from fat With regard to this suggestion it may be observed that it seems illegitimate to assume a double source for any substance appearing in the body until it is shown that its presence cannot be accounted for without such an assumption, in other words we must not lightly suppose the existence of two separate chemical reactions leading to one and the same result until it is shown that neither one alone is sufficient to explain the phenomenon If some of the sugar is formed from fat, may not it all be thence derived? Theoretical considerations lend considerable support to this suggestion It the first place, of all the substances within the animal body with the exception of glycogen fat is probably the most nearly allied to sugar From the point of view of theoretical chemistry the conversion of fat into sugar would seem to present no insurmountable difficulty The glycerine radicle of fat may be represented by the formula —

$$C_3H_5(OH)_3 \text{ or } \left\{\begin{array}{l} CH_2OH \\ CHOH \\ CH_2OH \end{array}\right.$$

By a series of substitutions of the group CHOH for one of the atoms of hydrogen we might theoretically get a substance —

$$\left\{\begin{array}{l} CH_2OH \\ CHOH \\ CHOH \\ CHOH \\ CHOH \\ CHO \end{array}\right\} \text{ or } C_6H_{12}O_6$$

—a typical sugar Secondly the production of sugar from fat has been experimentally demonstrated outside the body by Abderhalden and Rona who showed that if a mixture were made of liver tissue and blood with fats and oils some of these last were converted into sugar Thirdly some experiments performed by Luthje appear to prove that glycerine administered as food to animals may be converted into sugar within the system. *It seems certain therefore* that glycerine formed internally may undergo the same transformation That a liberation of glycerine takes place in pancreatic disease seems proved by the observation of Cammidge that it may appear in the urine under such conditions This observation, however constitutes a somewhat two edged argument, since if some of the glycerine formed within the body is excreted unchanged it might be asked why some should be converted into sugar Fourthly of the possibility of the conversion of fat into sugar within the body there seems no doubt since it has been shown that in hibernating animals such as the marmot —taking no food but merely absorbing a small amount of oxygen—there occurs an increase of the glycogen of the liver, with a corresponding decrease of the fat The fat must, therefore have been converted into glycogen and the further step to sugar is easy

If the origin of sugar from fat be really existent in diabetes it is of interest to note that both the substances most characteristic of the disease—the sugar and the acetone bodies—will be derived from destruction of the same tissue the acetone bodies arising from the fatty acid and the sugar from the glycerine radicle of the fat It is possible to bring forward various subordinate considerations drawn from the phenomena of natural and experimental diabetes to corroborate the suggestion of a disturbance of fat as the basis of the disease

1 In the first place the experiments made by Rosenfeld upon dogs which had been poisoned by phloridzin—experiments to which I have already alluded—suggest a serious disturbance of the adipose tissue in this condition which is closely similar to diabetes In phloridzin poisoning it seems possible that the fat is discharged into the blood from the stores of it existing in different parts of the body and is then taken up by the liver It must, however, be admitted that all the phenomena of phloridzin poisoning are as yet *inexplicable upon this or any other theory*

2 That a marked disturbance of the *body fat* takes place in dogs which have been deprived of their pancreases is shown by some experiments of Lombroso This observer was investigating the absorption of fat from the intestines in animals in which the pancreas had been removed and he found that more fat was excreted in the fæces than was given in the food, in other words, there existed an intestinal excretion of fat derived from the pre existing fat in the body Here, too it is clear that there must be a breaking down of the adipose tissue within the body of the animals These two conditions—phloridzin poisoning and removal of the pancreas—are the two most obvious forms of experimental diabetes, the probability that any special lesion which exists in both of them is also present in the natural malady is very considerable

3 But there are other phenomena pointing this way in diabetes itself *Thus it is not very rare in it to find that* the circulating blood is loaded with fat (lipæmia) This may occur in other conditions but it is most frequently met with in diabetes and is most marked in such cases It is reasonable to suppose in view of the conditions just alluded to as existing in experimental animals that here, too we have a rapid destruction of fat cells which not only give rise to sugar in the process of disintegration but allow a certain proportion of their contents to escape unchanged into the blood

4 In starving persons (tramps) and animals glycosuria is frequently met with (Hofmeister Hoppe Seyler) Under the same conditions it is found in animals that the fat content of the blood is increased (Fischer) This would appear to be another instance of a condition in which breaking down of fat is associated with glycosuria, while as previously mentioned the acetone in the urine is also increased in starvation so that the parallel with diabetes is very close

5 Further in diabetics it is not rare to find a fatty liver and the kidneys usually contain in their tubules some quantity of fat Fat is often found lying between the fibres of the muscles This fat may be simply taken up from the blood in which it exists in excess of the requirements of the tissues

6 The special cutaneous affection associated with diabetes —xanthoma—appears to consist in an accumulation of fat in the skin

7 The relationship of diabetes to obesity may perhaps be alluded to in this connexion, though it scarcely affords evidence in favour of the hypothesis Still the coincidence of the two conditions is of interest Fat diabetics as a rule *suffer comparatively* little from their malady It is possible on the one hand that many of them are not true diabetics but rather glycosurics Such patients suffer probably from no pathological destruction of fat due to deficient pancreatic secretion, but they may in presence of the increased amount of fat in their connective tissue produce by its normal disintegration an abnormal amount of sugar, for it is not impossible that the excessive destruction of fat in diabetes—like so many if not most pathological processes—is only a quantitative change in a normal process in other words that some breaking down of fat into sugar is a constantly occurring change natural to the organism but that it is increased to a harmful extent in diabetes owing to loss of the regulating action of the pancreas On the other hand in fat persons who become the subjects of true diabetes the supply of fat to start with being larger, they will be able to hold out longer against the drain of fat

8 Lastly the benefit derived in many cases from the use of fat in the diet may be connected with the destruction of the natural fat of the body produced by the disease

separately amounts to very

ater weight than

ual values But

if diabetes be really due to the ac [illegible] a poison which causes a breaking down of adipose tissue, it might not improbably also induce some defect in the processes by which these cells assimilate fat If they are poisoned they

in defective storage of [illegible] actual destruction of existing fat *If this be so* a bond will be established between the alimentary and the composite forms of the malady, without the necessity for the sharp distinction which

I emphasised for the sake of the argument in my first lecture.

Of the mechanism, if it be so called, of the storage and distribution of fat little seems to be known. It seems to be established, however, that cells of connective tissue do not directly swallow droplets of fat but that they break down the fat into some soluble material and absorb this, reconstructing fat within their own bodies. In the same way it is stated that in normal circumstances the fat within a cell is not directly discharged into the surrounding fluids, though this occasionally takes place; more often an analysis and a synthesis of the fat are effected, similar in all probability to those by which the process of storage was performed. It is not a very wild conjecture to suppose that the intermediate soluble substance in each process is either sugar or some closely allied substance while the comparatively rare direct discharge of fat from the cell may take place to an excessive extent in cases characterised by the appearance of liphæmia.

I would make no pretence to conceal the fact that the argument which I have set forth with regard to the source of sugar in diabetes is highly speculative and has little actual evidence to support it. It is quite possible, on the other hand, that since the protoplasmic constituents of the body contain both carbohydrate and fatty elements it may be by disintegration of proteid that sugar and even acetone are formed. The parallelism of the excretion of sugar, acetone, and nitrogen seems to point in this direction and the phenomena of phloridzin poisoning and starvation are susceptible of explanation on this basis. Lépine's observations are, however, important. The whole question is one which time and continued observation and experiment must be left to answer. At present, in spite of the immense amount of work which has been done on this subject, the results are contradictory and inconclusive.

Finally, if diabetes be due to the action of a poison which is normally neutralised by the pancreas, we are in the presence of two factors which interact to produce the disease. It is conceivable that in some cases the poison may be produced in excess of the power of the pancreas to neutralise it, even when the organ is only slightly affected, and that this may be the explanation of some of the cases in which we fail to find noteworthy anatomical changes in it after death. Of the seat of the formation of the toxin we have no indication, but it is not impossible that the benefits derived from restriction of carbohydrate diet arise less from mere limitation of the amount of sugar present in the blood than from the cutting off of the source of the poison which may be derived from carbohydrate metabolism. On the other hand, Dr. Lorand who was good enough to set his views before me in a personal interview, believes that an excess of animal food in the diet of a diabetic patient is harmful as tending to cause an excessive secretion of the colloid substance of the thyroid gland, this being, in his opinion, the poisonous substance at work. In view of this suggestion it would be interesting to observe carefully cases of obesity which are undergoing a course of treatment by thyroid extract in order to ascertain whether they exhibit glycosuria, but I have not had the opportunity of observing such a case since undertaking this inquiry.

In conclusion, then, I would venture to sum up the views which I have suggested as embodying a possible explanation of the phenomena of diabetes and the arguments by which they were reached.

1. Excess of sugar in the blood, which is the condition precedent of glycosuria, may be caused by over-production of sugar in the system or by diminished use or excretion. There is practically no evidence of either of these last processes. There is convincing evidence that at one stage, at all events, of diabetes there is increased production.

2. Over-production of sugar may depend upon some digestive irregularity, whereby more sugar than normal is poured into the blood from the food or upon manufacture of sugar from the tissues of the body. We have sufficient evidence that both these processes are at work in diabetes, in that at first the output in the urine can be controlled by limiting the diet, whereas later this is not possible. But whereas there are a considerable number of conditions in which sugar appears in the urine apparently as a result of absorption of additional sugar from the alimentary canal—these conditions being identical with diabetes only in the single fact of the appearance of sugar in the urine, while they run an entirely different clinical course—it is in diabetes mellitus alone that we have at any time evidence of formation of sugar from the tissue cells of the patient. This autolytic formation of sugar, if it may so be called, is the characteristic feature of diabetes in so far as the production of sugar is concerned.

3. It involves less of an assumption to suppose that this autolytic formation of sugar is present in diabetes all through the disease than to suppose that it ensues after a time as a result of the presence in the blood of excess of the very substance—sugar—into which the cells finally break down. The absence of proof of the existence of this process in the early stages of the disease, when the glycosuria is controlled by diet, may be due to the body possessing a certain power of utilising sugar in its nutritive processes, so that only the excess above a definite quantum appears in the urine.*

4. There is sufficient evidence available to establish beyond the possibility of doubt the fact that there is some connexion between the pancreas and diabetes. Although it is not yet proved, yet it is becoming increasingly probable that the pancreas is diseased in all cases of diabetes mellitus. An increasing bulk of evidence is also accumulating to show that the function of the pancreas which is in abeyance in diabetes is normally performed by certain special groups of cells known as the islands of Langerhans, which are distinct from the ordinary secreting cells of the gland, but which are not improbably formed from the acini. The special lesion of these islands—hyaline degeneration—which has been associated with diabetes by some writers, is not present in all cases of the disease and may be found (in a less developed state) in other conditions.

5. The action of the pancreas may be exerted in the direction either of supplying a substance necessary for the assimilation of sugar by the cells of the body or in that of counteracting a poison which in some way causes accumulation of sugar in the blood. There is little or no evidence in favour of the former possibility; in favour of the latter there are the results of experimental intoxication with phloridzin, with suprarenal extract, and with other substances, and a few inconclusive results obtained by injection of secretions derived from diabetic patients.

6. We are not yet in a position to state with any certainty what tissue in the body gives rise to the sugar formed in diabetes. The theoretical possibility that sugar may be derived from fat is supported by certain observations which prove that a serious disturbance of the adipose tissue exists in diabetes. Further, if this hypothesis be admissible a certain unity will be introduced into our conception of diabetes, the phenomena of which will be explicable as manifestations of a single process occurring in a single tissue.

7. Lastly, glycosuria as opposed to diabetes may be due to mere excess of sugar poured into the blood from the alimentary canal in excess of what the system is capable of assimilating; or it may be due to causes acting analogously to the diabetic puncture of Claude Bernard and leading to a discharge of sugar by the liver from its stores of glycogen.

If the views here set forth are correct it follows that in its earliest stage the diabetic process may constitute rather a predisposing cause of glycosuria than the actual cause of the phenomenon, since the breaking down of the tissue-cells into sugar is at first not more than sufficient to saturate the sugar-assimilating powers of the system. At this stage a slight increase of saccharine food will produce glycosuria—an increase which in a normal person would not have this effect. Similarly a slight nervous shock sufficient to cause the liberation of only a comparatively small quantity of glycogen from the liver would also augment the sugar present in the blood above the point at which it appears in the urine. In such a way the onset of true diabetes might be ascribed to a shock when in reality it was previously existent but unnoticed. As far as definition is possible, then, diabetes might be defined as an increased internal dissociation of tissue (possibly fat) into sugar, caused by a toxic substance which is produced in the course of normal metabolism and which is normally neutralised by the pancreas.

I venture to think that such an explanation harmonises better than what I may call the alimentary hypothesis with the trend of opinion in the matter of treatment. A comparatively few years ago, on the supposition that the sugar present was the poison at work, it was customary to put patients upon a severely restricted diet and to gauge the progress of the case entirely by the fluctuations in the amount of sugar present in the urine. It is now recognised that such a strict diet as was formerly fashionable is harmful to the sufferer and may even lead to an early appearance of coma, Indeed, the amount of sugar present in the urine is but a fallacious guide in estimating the condition of a patient. It is, perhaps, a criterion of some value when a patient first comes for treatment, as showing the stage which the case has reached and the amount of glycosuria which persists when the patient is on a restricted diet is some measure of the severity of the disease; but *a patient taking some carbohydrate food and excreting* more sugar may be in a better condition than one on a strict diet excreting a much smaller quantity. Nevertheless, we can hardly doubt that the presence of more than a certain percentage of sugar in the blood must by altering the density of the fluid, if not also in other ways, be detrimental to the organism; and we remain in presence of the old difficulty, how to feed the patient adequately and yet diminish the amount of sugar in the circulation. Nothing seems more certain with regard to the treatment of diabetes than that each patient must be a law to himself and that no general rule can be laid down for guidance. In some cases more and in others less carbohydrate food can be tolerated.

[illegible] pends more upon the
[illegible] upon the percentage

[illegible] and Gentlemen, for your patience in listening to these lectures and can only express my sincere regret that I have not been able to acquit myself more worthily of the responsible task which you did me the high honour of intrusting to me.

GALL-STONES AND CANCER.

BY G. R. SLADE, M.A., M.D. CANTAB., M.R.C.P. LOND.,
PATHOLOGICAL ASSISTANT AT THE LONDON HOSPITAL.
(*From the Pathological Institute of the London Hospital.*)

THE relation between gall-stones and carcinoma of the gall-bladder has given rise to much discussion in the past, and lately interest in the subject has been revived by the Bradshaw lecture on the Treatment of Cancer and by the subsequent correspondence. The point is of great importance in reference to surgical practice, and I trust that no apology is needed for the publication of the following observations which may help in the elucidation of the matter. This paper makes no pretence to be an exhaustive discussion of the subject but merely gives a brief account of a series of interesting cases that have occurred recently in the post-mortem room of the London Hospital and suggests certain conclusions that seem deducible therefrom. The figures are based upon the pathological records for the last 26 months, a period which coincides with the working of a new and *more accurate system of registration. Increasing interest* led me to examine the surgical registers also for the same period; but though I have ventured to touch upon the surgical as well as the pathological aspects of the question, my point of view has been essentially that of the morbid anatomist and any suggestions with regard to surgical practice are made with diffidence in the consciousness of trespass.

I must express my great indebtedness to the members of the surgical staff of the London Hospital for their kindness in permitting me to make mention of the cases under their charge.

PATHOLOGICAL ASPECTS.

1. *Frequency of gall-stones.*—In 2180 consecutive complete necropsies there were 33 cases in which gall-stones were either found in the gall-bladder at the post-mortem examination or had been removed by operation at a short interval before the patient's death. The low percentage proportion (1·5 per cent.) as compared with several similar series is probably explicable by the very large number of deaths occurring in the first three decades; for while Conradi[1] found gall-stones in 2·4 per cent. of 4000 necropsies on adults, Peters[2] found stones in only 0·62 per cent. of subjects under 30 years of age. In the present case it did not seem profitable to calculate the relative incidence at different ages, for the main interest lies in the absolute figures. In 17 of the 33 cases the gall-stones were "latent" and were discovered only at the necropsy. In the remaining 16 cases gall-stones and complications caused thereby were

[illegible] *ssociated with the presence*
[illegible] "latent" cases the wall of the gall-bladder was not thickened and its mucous membrane appeared perfectly healthy. No microscopical examination was made. In the remaining case the wall of the gall-bladder was thickened, shrunken, and closely moulded over three large rough gall-stones, so that no cavity remained. Microscopical examination of the wall showed carcinoma. (*b*) Of the 16 cases in which gall-stones produced *symptoms, in one case the* gall-bladder had been removed for carcinoma shortly before the patient's death. In three cases the condition was pronounced to be carcinomatous on the post-mortem table; in two instances the opinion was confirmed by microscopical examination; in the remaining instance the macroscopic appearance of the growth was such as to satisfy competent pathologists of its malignant nature. In 12 cases the wall of the gall-bladder presented an appearance which at the time of the necropsy was described as "chronic inflammatory thickening." In seven of these cases, unfortunately, no microscopical examination was made but in every one of the remaining five cases subsequent histological investigation showed the presence of carcinoma.

3. *Association of carcinoma with gall-stones.*—From the facts just stated it appears that carcinoma of the gall-bladder was found: (1) in 30 per cent. (10 in 33) of all cases of gall-stones; (2) in 56 per cent. (9 in 16) of all cases where gall-stones had caused symptoms during life; and (3) in 58·8 per cent. (10 in 17) of all cases in which at the necropsy the wall of the gall-bladder showed "inflammatory thickening." These figures are sufficiently startling but there can be no doubt that they understate the true proportion. It should be noted particularly that in this calculation the seven cases which were not submitted to microscopical examination have all been reckoned as non-cancerous, although to the naked eye they presented an appearance exactly similar to that of the five cases which were examined and proved to be carcinomatous. Since I began in all such cases to examine the wall of the gall-bladder as a matter of routine I have in no instance failed to find indubitable carcinoma; hence I do not hesitate to suggest that had all the cases been examined the percentage showing cancerous change would have been very much nearer 100 than 58.

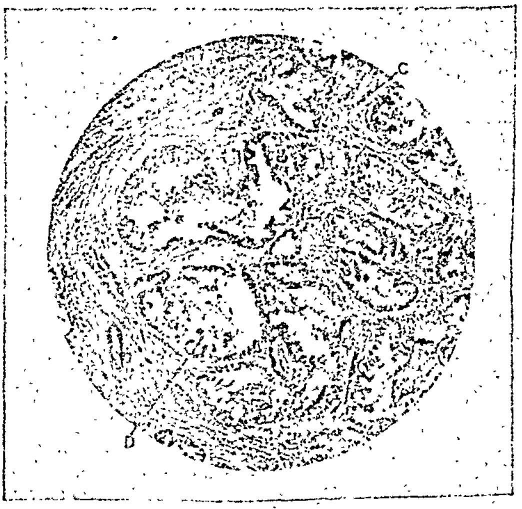

FIG. 4.—Columnar-celled carcinoma. C, Thick strand of dense fibrous tissue. D, Alveolus lined by columnar cells.

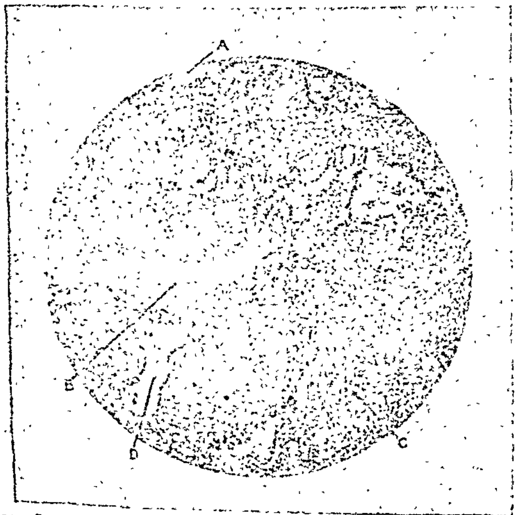

FIG. 5.—Columnar-celled carcinoma. A, Lumen of gall-bladder. B, Muscle bundle. C, Fibrous stroma. D, Alveolus lined by columnar cells.

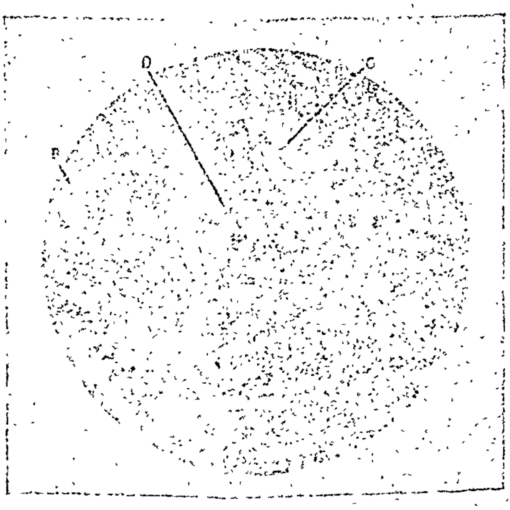

FIG. 6.—Cubical-celled carcinoma. B, Muscle bundle. C, Very dense fibrous tissue. D, Alveolus lined by cubical epithelium.

4. *Causal relation between gall-stones and carcinoma.*—This question is excellently discussed in Rolleston's recently published monograph on "Diseases of the Liver."[3] It is enough here to say that most authorities now agree in regarding gall-stones as cause and carcinoma as effect. The present series of cases lends strong support to this view of the relation if regard be paid to the following considerations: 1. In two cases symptoms attributable to the presence of gall-stones were of long duration. 2. In five other cases considerable fibrous thickening of the wall of the gall-bladder, in itself evidence of long-continued irritation, was associated with a very early stage of carcinoma. 3 In reference to the other cases it is to be noted that, while prolonged symptoms are valuable evidence, brief duration or absence of symptoms is of little importance, for it is notorious that gall-stones may be absolutely latent throughout.

It occasionally happens that no gall-stones are found in cases of carcinoma of the gall-bladder and this occurred in two instances during this period at the London Hospital. In one case, that of a woman, aged 61 years, it was impossible to determine accurately whether the growth had originated in the gall-bladder or the liver; the other case was that of a man, aged 70 years, who died very soon after admission in consequence of a street accident, so that there was no opportunity of inquiring for a possible history of previous biliary colic. In all such cases it must be remembered that absence of gall-stones at the necropsy is not positive evidence that the gall-bladder has never contained a stone and while it is conceivable that carcinoma of the gall bladder may occasionally arise apart from irritation caused by gall-stones there seems to be nothing in the two cases quoted to give unequivocal support to such a view.

In reference to the development of carcinoma it is an interesting point that of the 33 cases of gall-stones, in 16 the gall-bladders contained smooth stones and their walls were thin and healthy. In 17 (ten at least of which were carcinomatous) there was evidence of chronic inflammatory change in the wall of the gall-bladder and in the majority of these cases the calculi were rough; and these facts seem to suggest that the mere presence of gall-stones is insufficient to set up carcinomatous change and that some additional factor is necessary, such as: (1) a rough calculus, causing continued irritation; (2) infective cholecystitis, with or without the formation of pus; or (3) a combination of these conditions.

SURGICAL ASPECTS.

During the period under review abdominal section was done on 61 occasions because of the presence of stones in the gall-bladder and complications arising therefrom and in one additional case the patient's condition was such as to render operative interference hopeless. 17 of these patients died; in four cases a post-mortem examination was not permitted; in four cases a necropsy was made but the wall of the gall-bladder was not examined by the microscope, in nine cases there was carcinoma of the gall-bladder. 45 patients recovered; in two of these cases carcinoma was found in association with gall-stones and the gall-bladder was removed; of the remaining 43 cases the majority showed hydrops or empyema of the gall bladder and in no instance, so far as could be determined on the operating table, was there more than a simple inflammatory thickening of the wall of the gall bladder.

In view of the post-mortem findings already related it seems probable that some of these patients already had carcinoma of the gall-bladder in a stage too early for recognition by the naked eye; and I hope shortly to trace the after-history of these cases, though such a task is difficult and often disappointing in a hospital which serves a widespread and shifting population. It follows that of 62 patients in whom operation was called for owing to the presence of stones in the gall-bladder 11 (nearly 18 per cent) were shown either at the time of operation or by post-mortem examination to have carcinoma of the gall-bladder. And here I must emphasise the point already mentioned that these figures are minimal and in all probability are far below the true percentage ratio, for in this estimate every case in which a full examination was impracticable or was omitted has been accounted innocent, whereas every case that was submitted to a complete investigation proved to be carcinomatous.

The word "pre-cancerous" is in fashion at present and undoubtedly it has done good service in drawing general attention to the intimate connexion which exists between [illegible] development of carcinoma, not [illegible] also of the breast, the tongue, [illegible] But an indiscriminating use of the word may actually be a bar to progress and lead one to prejudge the issue in cases which are admittedly doubtful, and it would be at once more useful and more accurate to apply the term not to this or that diseased tissue which may or [illegible] easy to remove a piece of tissue for histological examination, it may be argued that the word "pre cancerous" is a convenient label for cases on the borderland between inflammatory hyperp[illegible] conventional use, tho[illegible] it be borne in mind [illegible]wen." But in the case[illegible]dinary investigation is impracticable the only recognisable "pre-cancerous" condition—if that word is to have any helpful significance—is the presence of gall stones in the bladder, and in view of the very frequent association of gall-stones with carcinoma and of the impossibility of recognising the early stages of carcinoma at the time of operation, I suggest that it would be sound practice, wherever it is surgically feasible and no obstruction of the common duct exists, to remove the gall bladder in all cases where "chronic inflammatory thickening" is found in association with gall-stones[4] There is here no possible objection on the score of mutilation such as might deter one from making a similar proposal with reference to the tongue and possibly also the female breast, and the gall bladder, like the appendix cæci, though doubtless serving some useful purpose in the human organism, must still be considered rather a luxury than a necessity of existence. I am conscious of the danger of drawing inferences from a somewhat limited experience and it may be that extended investigation will show that mine has been unusual, but should these conclusions be substantiated I would urge that cholecystectomy should be done at the earliest possible moment, not only on the general

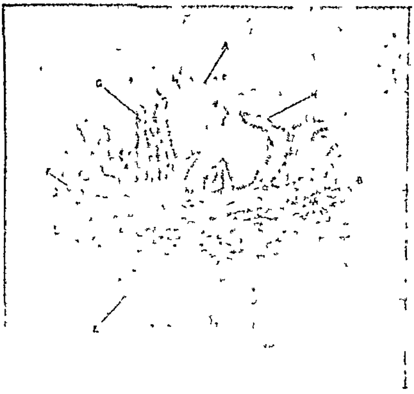

FIG 7—A semi diagrammatic representation of the normal gall bladder from a woman aged 53 years. It is introduced for comparison with the micro photographs of the cases of early cancerous change A, Lumen of the [illegible]

principle that prevention is better—and easier—than cure but especially because of the notoriously high mortality that follows operative measures even in early and still eradicable cancer of this organ—a point that is emphasised by the present series wherein of 11 patients with carcinoma who were submitted to operation no less than nine succumbed.

---

[3] Page 627 et seq

[4] A minor but not unimportant consideration is that removal would do away with the need of drainage and prevent the possibility of a biliary fistula remaining

Conclusions.—1. The association between carcinoma of the gall-bladder and gall-stones is very close. 2. Gall-stones may be looked upon as the determining cause of cancer of the gall-bladder. 3. Thickening of the wall of the gall-bladder is presumptive evidence of carcinomatous change. 4. Cholecystectomy should be performed whenever possible if any thickening of the wall of the gall-bladder be found at the time of operation.

Abstracts of eight cases of carcinoma of the gall-bladder which were examined by the writer, micro-photographs being appended in six of the cases.

CASE 1 (Fig. 1).—Female, aged 54 years. She had had several attacks of colic, each followed by transient jaundice, during the last nine months of life. At the operation three large stones were removed from the common duct. The gall-bladder was opened and drained. Death ensued in a few hours. At the post-mortem examination there was dilatation of the common and the cystic ducts. The cavity of the gall-bladder was diminished and its wall was thick and fibrous.

CASE 2 (Fig. 2).—Female, aged 64 years. A history of vomiting, increasing constipation, and pain in the right hypochondriac region for six weeks was obtained. No operation was performed. At the post-mortem examination 45 stones were found in the gall-bladder and one in the cystic duct. Near the neck of the gall-bladder was a nodule of firm growth which had begun to invade the liver.

CASE 3 (Fig. 3).—Male, aged 43 years. There was a history of acute onset of colic, with jaundice and enlargement of the gall-bladder Cholecystotomy was performed and numerous stones were removed. Intractable vomiting supervened and death followed speedily. At the post-mortem examination the gall-bladder was dilated and its wall was fibrosed.

CASE 4 (Fig. 4).—Female, aged 61 years. She had had attacks of colic at intervals for five years. At the operation the gall-bladder was opened and many stones were removed. Death ensued five days afterwards. At the post-mortem examination a mass of growth was found projecting into the cavity of the gall-bladder at the fundus, and the greater part of the wall was infiltrated.

CASE 5.—Male, aged 60 years. There was a history of a transient attack of jaundice two years before death, with subsequent passage of a gall-stone by the anus. Severe colic and vomiting occurred 20 months later, followed by jaundice, which persisted. At the operation a stone was removed from the common duct. At the necropsy the gall-bladder was represented by a small cavity with greatly thickened fibrous wall, closely adherent to the surrounding structures. The microscopic section showed early cancerous change.

CASE 6.—Female, aged 43 years. A history of illness of one year's duration, with symptoms suggesting pyloric obstruction, was obtained. At the operation the stomach was found to be greatly dilated and there were dense cicatricial adhesions just beyond the pyloric ring. Posterior gastro-jejunostomy was performed. At the necropsy the gall-bladder contained several large gall-stones and its wall was indurated and enormously thickened. The mass was adherent to the first part of the duodenum and caused great narrowing of its lumen. The microscopic section showed early cancerous change.

CASE 7 (Fig. 5).—Female, aged 51 years. A history of attacks of colic and vomiting for six months was given. There was a palpable mass in the region of the gall-bladder. Exploratory abdominal section showed that operative treatment was impossible. At the necropsy the gall bladder was replaced by a large mass of indubitable new growth in which were several gall-stones.

CASE 8 (Fig. 6).—Female, aged 46 years. There was a history of attacks of abdominal pain and vomiting for several months, followed by
of the gall-bladder. At the operation
ontain pus and numerous gall-stones
all at the fundus was a fungating mass
was performed. Death was due to

London Hospital, E.

THREE CASES ILLUSTRATING THE CONDITION OF THE SMALL INTESTINE SOME YEARS AFTER EXTENSIVE ENTERECTOMIES.[1]

BY ARTHUR E. J. BARKER, F.R.C.S. ENG.,
SURGEON TO UNIVERSITY COLLEGE HOSPITAL.

THERE must be few surgeons now who do not recognise the peculiarly disastrous effects of paralysis of the bowel in advanced intestinal obstruction. These make themselves evident to the operator in many ways before, during, and after the relief of the obstruction, and are unfortunately so often seen that they require no comment here. But few of us are likely to have many opportunities of seeing the effects of this paresis on the *living* gut *years* after the relief of severe obstruction. Three such opportunities have fallen to my lot quite recently and it seems desirable that they should be put on record, emphasising, as they do, some points of fundamental importance in the treatment of acute intestinal obstruction.

The two first patients concerned were both women. They were admitted some years ago for gangrenous femoral herniæ and in both I was obliged to resect long tracts of small intestine in order to obtain relatively sound tissue for the anastomosis. Both made a satisfactory recovery from these operations but were readmitted in October, 1904, for operations in the course of which it was possible to examine the original seat of the enterectomies. In both it was most interesting and instructive to observe that, though the communication between the two portions of the bowel was perfect and as wide as possible, the afferent or proximal portion still showed unmistakeable signs that it had not yet recovered its former tone as contrasted with the efferent or distal portion which was normal. The significance of this observation appears to me very great both from a medical and a surgical point of view and so far as I know has not yet attracted attention at home or abroad.

A description of the first operation in each case has already been published and it is only necessary here to state that, in the first, 18 inches of small gut were removed in June, 1899, on account of a gangrenous femoral hernia. This was done through the femoral ring, Poupart's ligament being divided to permit of the reduction of the anastomosed bowel and ligatured mesentery into the abdomen. The junction was "end-to-end." In the second case, also of gangrenous femoral hernia but in a much graver condition, the gangrenous loop was on Feb. 23rd, 1903, cut away below the femoral ring and then the ligatured ends were passed into the abdomen and brought out through a median incision where six and a half feet of damaged small intestine were taken away from the proximal portion and a *lateral* anastomosis was made.

Case 1 was readmitted on Oct. 24th, 1904, for the radical cure of double hernia—*i.e.*, *five and a half years after* the enterectomy. A large femoral hernia was found to exist on the left side in the seat of the first operation and a moderate-sized inguinal hernia on the right The patient was very stout. The left hernia contained much intestine the movements of which could be seen through the thin coverings and was obviously due to the weakening of Poupart's ligament by its division in the earlier operation. On Oct. 27th the usual operation was done for the radical cure of this hernia.

When the sac was opened I took the opportunity of examining the contained bowel before it was reduced in the hope of finding the anastomosis. Fortunately, it was there and its condition could be demonstrated to a large number of those present in the operating theatre. When drawn forward and laid on a layer of white gauze we could see that the two portions lay accurately in line and that the junction was as smooth as the rest of the bowel and without a trace of adhesion to any other structure. It was marked by faint white streaks indicating the seat of the sutures all of which had completely disappeared. There was not the slightest sign of contraction or narrowing. But what struck us all most forcibly was that all the bowel distal to the anastomosis was in a state of very active vermicular movement and was contracted to a small size while that above the junction was smooth, sluggish, somewhat thinner, and of considerably larger lumen than that below. I drew the coil forward and stretched it gently but this made no difference in the relative sizes of the two portions. It was, in short, evident that the original paralysis of the bowel above the obstruction had left behind it a certain want of tone in the muscular wall of the proximal portion or blunted nervous irritability. The only other trace of the original operation was a tiny adhesion of an adjacent coil to the mesentery close by which I did not think it worth while to divide. After clearing up these points of interest the bowel was reduced and the radical cure was completed. The other inguinal hernia was operated on a week later on which occasion the first was found blamelessly healed per primam. The patient left hospital well on Nov. 26th.

Case 2 was readmitted on Oct. 14th, 1904, suffering from intestinal obstruction of some days' standing. Suspecting a band of adhesion from the former operation in February, 1903, I opened the abdomen above the median scar and found several very firm adhesions between the stump of the mesentery and the lower end of the scar. Round these

---

[1] A paper read at the Clinical Society of London on March 24th, 1905.

adhesions some coils were kinked These were released and I drew out the intestine and obtained a good view of the old lateral anastomosis of 21 months before Here too, it was extremely interesting to note that though the opening between the two portions was widely patent the proximal, as far up as it was exposed, was of considerably larger size than the distal Both were contractile but the lower more so than the upper Several adhesions were left undisturbed and the abdomen was closed Convalescence was uneventful and the patient left hospital quite well on Nov 7th

These two observations made *intra vitam* on patients suffering from no general disease and quite healthy at the time except for the local condition, fill up to a certain extent a gap in our knowledge as to the changes which take place in an intestine above an acute obstruction, and as to the *period during which these effects may remain after the latter* has been relieved It might at first sight appear almost incredible that evidence of want of tone in the bowel should exist several years after the cause had been removed But we see the same thing elsewhere frequently For instance who does not know the cold congested appearance of a limb which perhaps months or even years before has been the seat of some inflammatory septic condition such as erysipelas In this case the tissues have been saturated with toxins just as the walls of the intestines have been and the result has been atony of the coats of the vessels of the

even paræsthesia

the distal portion of

nergetically under the

the proximal part up

to the line of anastomosis was sluggish and almost quite indifferent to the same stimulus And when we come to reflect upon what actually takes place in the walls of the intestine above an acute strangulation we must admit that there is little cause for wonder if the *effects should last for a long* time Should the obstruction remain unrelieved for long we all know the dilatation of the gut above which follows accompanied at first by increased peristalsis but terminating before long in paresis or complete paralysis This paralysis is probably not entirely due to exhaustion of the muscular coats from overstrain but is the result of the saturation of all the tunics of the bowel with toxins developed in the fermenting contents That this is so seems to me proven by the fact which every surgeon must have observed over and over again—i e , that when a bowel is examined above a bad obstruction it will be found in many cases œdematous for several feet on the proximal side of the strangulation This need not be due to the presence of ulceration at the point This condition, which is so common in the bowel just above an obstruction and for a foot or two upwards, might explain the œdema locally But far above this the œdema extends where no breach of surface can be detected, at all events with the naked eye

In Case 2 I found œdema more than six feet above the strangulation when I was making the anastomosis at that point We see, also further evidence in a submucous ecchymosis associated with the œdema In another case, where I removed five and a half feet of small intestine for acute strangulation the œdema was so marked in the proximal portion while the "end to end" anastomosis was being made that I was in serious doubt as to whether the vitality of the bowel was sufficient for repair Happily it proved to be so and the patient made an excellent and uninterrupted recovery That such toxins are intensely irritating on other surfaces is well seen on the skin soon after an artificial anus has been made to relieve a bowel damaged by acute obstruction In a case recently operated on for this condition the ulceration of nearly the whole of the abdominal surface was the most formidable complication in the subsequent treatment of the case Again, the œdema is not seen in the earlier stages of acute obstruction before the ferment toxins are developed in the retained contents but it is found in neglected cases in increased intensity and extent in proportion to the duration of the obstruction and possibly also in relation to the quality of the aliment previously given to the patient But though I have been for years alive to these changes in the bowel wall and have planned my resections and "short circuit" operations with due regard to them I confess I was hardly prepared to find evidence of more or less paresis of the proximal part some years after the obstruction had been relieved

This has all to be taken into account also in cases where we elect to perform a short circuit round an obstruction as Case 3 shows, *which has come under notice since this* paper was sent in to the society This was a case of a man, aged 29 years who was admitted into hospital two years ago for acute obstruction grafted on a chronic condition which we diagnosed to be probably cancerous in the hepatic flexure of the colon He had stercoraceous vomiting and much distension &c I opened the abdomen below the navel and found greatly distended small bowel This was slit open over a basin and gave exit to large quantities of gas and fluid fæces It was then possible to explore further and I found the cæcum and ascending colon distended and the descending colon and sigmoid flexure empty and shrunken The obstruction, therefore, was obviously between the two regions I then united the lower part of the ileum to the sigmoid flexure side to side and closed *the evacuation opening Recovery followed but the man would* not stop in hospital for the resection of the growth but promised to return as soon as he had arranged his business affairs However, he did not appear until about three weeks ago When I opened the abdomen last Thursday week the growth was found too extensive and fixed under the liver to justify removal and I closed the wound But before doing so the "side to side' junction was examined and the place where the evacuation opening had been made and closed Both were in perfect condition no traces of the black thread sutures being seen *and not* the smallest suspicion of adhesions to surrounding parts where the bowel had been stitched and manipulated , all was smooth over the white lined cicatrices Nevertheless, as in the other cases, the proximal and in this case the distal portion between the anastomosis and the cæcum about eight or ten inches were still in a state of atony and contrated markedly with the upper part of the ileum and jejunum which could be seen contracting in active vermicular action The man s health had been excellent since *the first operation and his bowels quite regular* and motions normal Incidentally I may express the regret that this poor fellow did not redeem his promise of returning for the removal of the growth before it grew too extensive and fixed for excision For he is still in good condition, though now losing colour and strength from generalisation and complains of nothing else

When we find such changes in the intestines as those just described even years after the cases have been relieved we are more than ever *driven to the conclusion that in* acute strangulation we must operate before they can have had time to develop And if this be impossible we must not hesitate where resection is necessary to remove large tracts of bowel in order to get well above the paralysed portion, saturated as it is with toxins and so devitalised In another respect the first two cases offer us a valuable hint by contrast In Case 1 the resection was performed through the femoral ring and the difficulty of doing so was well exemplified It was not so much the "end to end ' suture which gave trouble though this is much easier through an abdominal wound *But when the mesentery corresponding* to the 18 inches of resected bowel had been tied off and sutured side to side a mass was formed of such a size that it was impossible without the exertion of more force than the sutured bowel would stand to reduce it through the femoral ring I was therefore obliged to enlarge the opening by dividing Poupart s ligament in order to get it back The result of this was a large femoral hernia in course of time Taught by this I determined in the next case to cut away the gangrenous loop after tying the bowel above and below and then to pass the stumps carefully covered with gauze into the abdomen and then out again through a median incision in the abdominal wall for the performance of the extensive enterectomy (six and a half feet) which was necessary Here of course, there was no trouble with the mesentery in slipping it under Poupart's ligament and the femoral opening could be closed by a few stitches The result is that up to the present now more than two years there is no trace of hernia which was so marked in Case 1 This procedure of suturing the stumps and returning the bowel after removal of the gangrenous loop and performance of the rest of the enterectomy through a median incision appears to me the typical method of dealing with the condition

This paper is a natural sequel to some papers on Enterectomy for Gangrenous *Hernia published in* THE LANCET in 1903[2]

[2] THE LANCET May 30th (p 1495) and June 6th (p 1576) 1903

A FURTHER NOTE ON THE RELATION BETWEEN VARIOUS ATMOSPHERIC CONDITIONS AND THE OCCURRENCE OF CEREBRAL HÆMORRHAGE.

By JAMES W. RUSSELL, M.A., M.D. CANTAB., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO THE BIRMINGHAM GENERAL HOSPITAL.

IN THE LANCET of Jan. 28th, p. 222, I tried to discover whether any positive evidence could be obtained in favour of the suggested influence of variations in atmospheric pressure and temperature in determining the onset of cerebral hæmorrhage, with the result that in a series of 128 consecutive cases admitted into the Birmingham General Hospital five out of every nine were found to occur on days on which the barometric pressure was above the average. Temperature was not found to exercise any influence but a large preponderance of cases occurred on days on which a wind pressure below the average was recorded. In a letter to THE LANCET of Feb. 4th, p. 322, Dr. W. H. Symons pointed out that the inequalities shown by my figures would be satisfactorily explained if there existed an actual preponderance of days of atmospheric pressure above the average in the years involved in the inquiry. This very obvious explanation had not occurred to me and on putting it to the test I find that it completely accounts for the excess of cases observed not only on days of high barometric pressure but also on days of low wind pressure. The point is not one of great importance, as the evidence obtained was at most inconclusive; but as my figures are, so far as I know, the only ones existing on the subject I feel bound to correct the inferences tentatively drawn from them. I have the less regret in doing so as my paper was not written with any desire to make out a case in favour of the suggested connexion; and that the present results are far more in accord with physiological probabilities

In the 12 years under examination there were 4377 days on which the *atmospheric pressure was above the average as* compared with 2043 days when a pressure below the average was recorded. This preponderance of days of higher pressure would account for the occurrence of 68 out of my 128 cases on those days, leaving 60 for days of pressure below the average level. The actual numbers obtained were 71 and 57 respectively, and it therefore seems clear that the excess of cases occurring on days of higher pressure is entirely accounted for by the larger number of those days existing in the years under examination, and that my cases afford no evidence in favour of the suggested influence of high barometric pressure in causing cerebral hæmorrhage

The figures obtained with regard to variations in pressure do not correspond quite so closely. On taking the pressure of each day in relation to that of the days preceding and following it, and using the same symbols as in my former paper, I get the following results.—

	<>	<	>	><
Actual number of days in the 12 years	988	1148	1176	971
Corresponding proportion for 128 cases	30	34	35	29
Actual distribution of cases as published in former paper	29	42	28	29

It appears, therefore, that a small excess of cases occurred in the course of a steadily rising barometer beyond that accounted for by the preponderance of days with that arrangement. It is hardly, however, large enough to carry much weight as evidence of a causative effect.

In the matter of temperature the days are very evenly distributed as regards the average. Thus in the months concerned in one-third of the total number of the cases there were 334 days on which the temperature was above the average maximum for the month, and 335 on which it was below the average. I did not, therefore, consider it worth while to continue the calculation, and the results of my former figures, which showed no causative effect of temperature, may be taken as correct. The apparent effects of a low wind pressure are similarly explained by the large excess of days with a pressure below the average. In the 12 years concerned there were 2973 days of low, as compared with 1343 days of high, pressure. This gives a distribution in 128 cases of 88 and 40 respectively. The actual figures obtained were 92 and 36, a sufficiently close approximation.

It thus seems to be established that actual height of barometric pressure, temperature, or wind pressure exercises no influence in determining the onset of attacks of cerebral hæmorrhage.

Birmingham.

PLAGUE IN CATS.

By WILLIAM HUNTER, M.B., C.M. ABERD.,
GOVERNMENT BACTERIOLOGIST, HONG KONG.

THE writings of past ages tell us that during epidemics of plague domestic pets were not spared the disease. It is only within recent years, however, that the occurrence of plague in animals such as cats, which are intimately associated with man, has attracted attention. In fact, until the question of rat plague was raised the presence of plague in animals was practically lost sight of and regarded of no significance in reference to the spread of the disease. With the knowledge of the presence of widespread rat plague and the fact that cats frequently devour these animals, the possible rôle played by cats in the dissemination of plague amongst human beings would appear to be of importance. Few accounts of natural plague infection in cats are to hand. The various plague commissions make mere mention of cat plague. They regard these animals as only slightly susceptible to the disease. In consequence they conclude that so far as the spread of plague is concerned cats are of no great importance.

Such an answer to the question of plague in cats is only partly true. Cats, when compared with many other animals, do appear relatively insusceptible. Their importance in the dissemination of plague, however, is underrated when the subject is viewed in the light of recent experience. The disease in cats is rare but the possibility of the occurrence of plague in domestic pets in plague-infected districts must not be [illegible] duced plague in cats would a [illegible] The disease can be induced but much depends upon the method of incorporation of the virus. The German Plague Commission reported upon the effects of cutaneous and subcutaneous inoculation of these animals. Beyond a slight febrile reaction nothing definite was obtained. All the cats recovered. The commission concluded that cats were relatively insusceptible to plague. The results of Albrecht and Ghon were more definite. They fed cats on plague-infected material. Several of the animals died as the result of plague infection. The type of disease reproduced was septicæmic. In one or two instances a bubo was found in the submaxillary region. Kolle also fed cats with cultures of plague. Several of the animals died from plague. Wilm, in his report on plague, fed two cats with pieces of a plague bubo. The animals were sick for several days. Great emaciation of the cats was noted. Ultimately both animals recovered.

From these investigations on experimental plague infection in cats it is evident that infection per os gives the most constant results. By this method cats would appear to contract the disease. The question of a lethal termination probably depends upon the virulence of the infecting material used for purposes of inducing the infection. As regards spontaneous plague infection in cats, extremely little would appear to be known. The Indian Plague Commission simply notes the fact and dismisses it in a sentence. In Sydney, Ashburton Thompson has reported the presence of plague infection in cats. He draws attention to the dangers attached to such a focus of infection.

An excellent opportunity of studying spontaneous plague infection in cats occurred recently in Hong-Kong. The history of the epizootic is the following. During the systematic collection of rats, dead and alive, in Kowloon for bacteriological examination many of those caught in the godowns were found to be plague infected. A week or two after rat plague had been found the servants of the Godown Company reported the death of several of their cats which were kept on the rat-infected premises. The bodies of these cats were sent to me for bacteriological examination. This was carried out as completely as possible, the morphological and cultural tests being typical of the bacillus pestis. The stalactite test was also positive. The cat mortality increased. I requested that all cats, sick or dead, should be forwarded to me. The sick cats were kept under observation in isolation. Experiments were made in regard to the modes of infection in cats and the symptoms of the disease were noted as carefully as possible. My investigations showed that cutaneous and subcutaneous inoculation do not give definite results. Feeding cats with plague buboes and pieces of human spleen crowded with plague bacilli give more or less constant results. The following experiments were undertaken.

Cat No. 1.—The animal was healthy and was kept under observation for at least 14 days. It was inoculated subcutaneously with one cubic centimetre of emulsion of plague bacilli on agar. After 24 hours the previously normal temperature rose to 102° F. The animal refused food. A doughy swelling occupied the site of inoculation. After 72 hours, the temperature being 103°, the animal had vomiting and diarrh[illegible] size but now felt [illegible] were found in the [illegible] from a considerabl[illegible] favourably. The swelling developed into an abscess containing abundant staphylococci but no plague bacilli could be found.

[illegible] e as in No. 1. [illegible] a large femoral [illegible] as decidedly ill. [illegible] diarrhœa. The [illegible] nwards the condition became aggravated; the temperature was irregular and maintained about 102°-103°. The abdomen was distended and tender to touch. The diarrhœa continued to the last. No tenderness was noted in the axillæ or groins. Emaciation was also a marked feature. Death took place in seven days. The fæces were rubbed into the shaved abdomen of a guinea-pig. This animal died from plague in four days. A post-mortem examination was made. There was great congestion of all organs and tissues. Hæmorrhages of [illegible] mucous membrane showed great congestion, swelling, and slight erosion. Petechiæ were scattered throughout its entire length. The solitary follicles were enlarged and in some parts of the gut the condition resembled severe follicular enteritis. Plague bacilli were found throughout the body. The organism was isolated and subjected to the well-known tests.

[illegible] its were not made owing [illegible] godowns which I had at [illegible] of these animals I found that plague may be either acute or chronic. The following is a *résumé* of my results:—

Acute cat plague.—Symptoms: These are usually present within 24 hours. Food is refused. The hair of the animal becomes ruffled. Diarrhœa and vomiting are among the early symptoms. Weight is lost rapidly. The abdomen is distended and often tender to touch. Towards the end of the disease great weakness and even paralysis of the extremities are present. Death usually occurs in from two to six days.

Post-mortem appearances.—Bubonic swellings may be found, especially about the neck and the mesentery. The lymphatic glands in general are enlarged and show marked cortical injection. The general condition throughout the [illegible] The stomach is congested, particularly on its mucous surface. The latter also shows the presence of innumerable [illegible] e mortem [illegible] n general [illegible] until the ileum was reached. This part of the gut was the seat of many small hæmorrhages. The mucous surface was red and thickened. The latter was chiefly due to œdema. The solitary follicles were visible, being pin-head in size and greyish-yellow in colour. Small areas of necrosis were present [illegible] containing myriads of plague bacilli. The type of disease was in all instances septicæmic but special tendency was shown on the part of the plague bacilli to collect in the lymphatic apparatus.

Chronic cat plague.—The most prominent symptom is great emaciation. Buboes may be found in various situations of the body, especially about the neck. These are chronic in growth and are a[illegible] ing infiltration. [illegible] charging thick or [illegible] mouths. The con[illegible] marasmus."

The following conclusions appear to be justified from the various observations and experiments on plague-infected cats. 1. Cats suffer from plague. 2. The disease may be acute or chronic. 3. The ty[illegible] 4. These animals may occas[illegible] 5. In [illegible] in cats [illegible] iew. 6. In plague-infected areas cats probably become infected through plague rats and mice which they devour as food.

Hong-Kong.

SUPPURATIVE PERIOSTITIS FOLLOWING TYPHOID FEVER.

BY WILLIAM H. BATTLE, F.R.C.S. ENG.,
SURGEON TO ST. THOMAS'S HOSPITAL;

AND

LEONARD S. DUDGEON, M.R.C.P. LOND.,
SUPERINTENDENT OF THE CLINICAL LABORATORY AND DEMONSTRATOR OF CLINICAL PATHOLOGY, ST. THOMAS'S HOSPITAL; ERASMUS WILSON LECTURER, ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THERE are now many instances of the occurrence of bone lesions after typhoid fever in the discharge from which the bacillus typhosus has been demonstrated. There are some unusual features in the following case which make it of exceptional interest. Most of those recorded have been affections of the tibiæ or ribs and the extent of bone involved has not been so extensive as here. It is unusual, also, to have an inflammatory attack of the bone which has arisen and subsided at a time when the bacilli would presumably be more active than at a later date. It is also noteworthy that although the periosteum was completely separated from the bone for some distance up the shaft and in the whole circumference the recovery of the limb without necrosis of bone has apparently been assured.

The patient was admitted into the Leopold ward of St. Thomas's Hospital on Oct. 28th, 1904, and was discharged on *Dec.* 21st, 1905. (The following is taken from the notes by Mr. Finch.) The patient was in the George ward, under the care of Dr. Hector W. G. Mackenzie, from July 7th to Sept. 10th, 190[illegible] illness had commenced on June [illegible] ing, and pain in the back and ab[illegible] ptoms of perforation developed at 1.30 P.M. Abdominal section was performed at 7.15 P.M. and a perforation of the ileum was sutured by Mr. Battle. The patient was readmitted on Sept. 18th for pain in the right femur and knee; this was treated with iodide of potassium and local applications and he was able to leave the hospital in about three weeks. Since that time he had remained well, but was readmitted some months after for pain in the abdomen which followed a slip whilst carrying a sack of coals. The present illness began four weeks before admission with pain in the lower half of the right femur. This pain was of a gnawing character, sometimes shooting down the leg; it was worse at night and kept the patient awake.

On admission the lower third of the right femur was uniformly enlarged and was extremely tender on pressure. The skin in front of the thigh in this situation was red from the application of mustard poultices before he came to the hospital. His temperature was 102·2° F. There was no evidence of syphilis in any part, the glands in both groins were easily felt, and there were a few scars on the legs, but these presented nothing characteristic. Skiagrams showed thickening of the lower half of the femur. On Nov. 3rd the pain was stated to be somewhat better than on admission; the patient perspired freely at night, whilst the temperature varied from 100° to 101° in the day. He had required chloralamide to make him sleep. Iodide of potassium in increasing doses was given without any benefit. Severe pain continued and the temperature remained elevated, not below 99° in the morning or above 101° in the evening. No apparent change had taken place in the condition of the bone which continued to be extremely tender and uniformly enlarged. On the 16th an incision was made on the outer side of the thigh above the knee. Thickened periosteum was incised and thick yellow pus immediately sprang into the wound. The periosteum was separated from the shaft all round and the bone was generally roughened where exposed. The operation wound was drained and the pain was quickly relieved by the incision. When the patient left the hospital the wound was soundly healed and he has now resumed his work.

Bacteriological report.—A culture tube of broth was inoculated with the pus from the periosteal abscess and incubated at 37° C. for 24 hours. Marked turbidity and a slight flocculent deposit in the culture tube were observed at the end of the first 20 hours. Film preparations were made from the culture and were stained by Gram's method. Short thin bacilli, which were Gram negative, were seen in the films. The original culture was now plated on the surface of jelly by the stroke method. Large numbers of pale bluish-white colonies with an irregular margin, and gradually sloping from the centre towards the periphery, were seen on the surface of this medium at the end of 24 hours at 22° C. These colonies were found to be similar in most respects at the end of 48 hours. We consider this to be a fact of very great importance, as although the surface colonies of certain strains of the colon bacillus are very similar to the colonies of the bacillus typhosus yet the surface colonies at the end of 48 hours are quite different, owing to the much more rapid growth of the colon bacillus. The surface colonies of the colon bacillus at the end of 48 hours are much denser and darker than the typhoid colonies, the irregular margin is much more opaque, and the colonies instead of gradually sloping from the centre towards the periphery, as in the case of the bacillus typhosus, terminate abruptly and thus give quite a different appearance to that which is seen at the end of 24 hours. Numerous colonies from the surface of three gelatin plates were emulsified in 0·85 per cent. solution of normal saline and the emulsions were then tested with positive typhoid serum. The bacilli from each colony were found to be actively motile, while on the addition of typhoid serum, using a dilution of 1 in 50, complete loss of motility and complete "tight" agglutination were obtained in the case of every colony which was examined. The agglutination of the bacilli and the complete loss of motility took place immediately. We consider this means of examining colonies of suspected typhoid bacilli to be of the utmost value as we have never seen agglutination of the bacillus coli with positive typhoid serum such as occurs in the case of the bacillus typhosus, or even with dilutions of 1 in 10, although we have examined some hundreds of strains of the colon bacillus chiefly obtained from the peritoneal cavity. It must be remembered that by this means valuable information can be obtained at the end of 24 hours regarding the nature of a suspected bacillus. Three of the surface colonies from the jelly plates were subcultured into broth and afterwards large numbers of tubes of various media were inoculated from these broth tubes.

The following are the cultural characteristics of this bacillus:—

Agar.—Pale streak with a slightly irregular margin and moist surface. The streak became more opaque and the growth more extensive as time advanced.

Glycerine agar.—Very similar to the growth on agar.

Glucose agar shake.—There was no gas production at the end of one month's growth at 37° C.

Gelatin slant.—Slight pale bluish white streak with a feathery edge was seen at the end of 24 hours' growth.

Neutral red jelly.—Appearances of growth similar to those seen on jelly. No alteration of colour and no liquefaction of the medium had appeared at the end of one month.

Glucose jelly shake.—No gas formation had occurred at the end of one month's incubation.

Litmus mannite jelly shake, litmus cane sugar jelly shake, litmus maltose jelly shake, and litmus lactose jelly shake at 22° C.—The colour of the litmus was unaltered and there was no gas production.

Litmus milk.—This medium was acidified at the end of three days' growth at 37° C., but the milk was not even thickened at the end of one month.

Milk.—Unchanged.

Potato.—Very slight moist pale growth formed on the surface of potato in 48 hours, but it never increased.

Peptone water.—No indol production at the end of 14 days.

Neutral red broth.—A good growth was seen in this medium but there was no alteration of colour at the end of one month.

Glucose broth (anaerobically).—Good growth without any production of gas.

McConkey's medium.—Sodium-taurocholate-litmus-glucose broth culture tubes were inoculated with the bacillus in question and then incubated anaerobically at 42° C. The medium was acidified in 48 hours but there was no evidence of any gas formation.

Agglutination tests.—With positive typhoid serum. Dilutions 1 in 20 and 1 in 50: complete loss of motility and complete "tight" agglutination occurred immediately with each dilution. Dilution 1 in 100: similar result at the end of 30 minutes. With patient's serum. Dilution 1 in 20: diffuse loose clumping and slight loss of motility in 30 minutes. Dilution 1 in 50: very slight loose clumping and very slight loss of motility at the end of 30 minutes.

Professor W. Osler[1] mentions that six cases of "bone lesions" came under his notice among the sequelæ of typhoid fever in the course of one year. In this country, however, bone lesions directly due to the typhoid bacillus appear to be rare. In Keen's monograph on the surgical complications and sequelæ of typhoid fever he gives the bacteriological report of 51 cases of the bone lesions of typhoid fever. In 38 instances the bacillus typhosus was recovered, while in 13 examples the more common pyogenic organisms were found. The case which we have described is of considerable interest owing to the fact that the bone abscess contained the typhoid bacillus in pure culture more than two years after an acute attack of typhoid fever. There is only one other point to which we wish to draw attention—viz., the agglutinative property of the patient's serum. Mr. H. S. D. Browne and Dr. K. E. Crompton,[2] working in the clinical laboratory of St. Thomas's Hospital, found that out of a total of 68 cases only three gave a positive reaction—i.e., complete loss of motility and large tight agglutinations within a period of 30 minutes with dilutions of 1 in 20 and 1 in 50, while of these three cases the patient's serum in one instance was obtained two months after the acute illness had subsided. These authors mention that if they had considered a dilution of 1 in 10 to be a positive reaction then their sum total of positive cases would have amounted to 11, but they very wisely refrain from including such low dilutions amongst their positive results. Fison[3] has stated that he has obtained a positive reaction with dilutions of 1 in 2 and 1 in 9 in 18 out of a total of 21 cases examined three months to eight years after the primary illness. Rénard[4] examined 104 cases, 35 of which gave positive reactions, in five instances 20 years after the attack. This observer, however, was content with a dilution of 1 in 10, except in one of his cases in which a dilution of 1 in 40 was employed. Dr. C. G. Seligmann[5] failed to obtain a positive reaction, even with a low dilution of 1 in 20, in Dr. H. C. Jonas's case of multiple typhoid abscesses two years after the original attack. It must be quite obvious, however, that although positive reactions with such low dilutions may be of some interest they cannot be of the slightest practical value. Mr. Browne and Dr. Crompton have definitely shown that it is quite the exception for the true positive typhoid agglutinative reaction to last for more than a short period after the acute illness has subsided, and that it does not remain for months or even years afterwards, as is so often incorrectly taught. Our own experience is in accordance with the views of these observers.

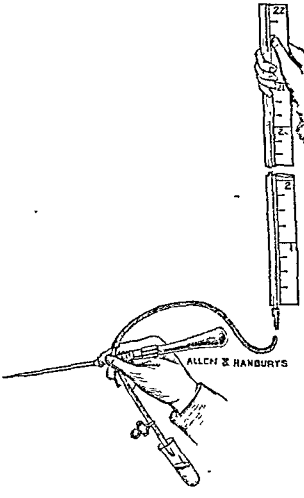
A CEREBRO-SPINAL MANOMETER.[1]

By FRANK C. EVE, M.D. CANTAB., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN, VICTORIA HOSPITAL FOR CHILDREN, HULL; LATE HOUSE PHYSICIAN, HULL ROYAL INFIRMARY.

I WAS led to devise this simple instrument for measuring the cerebro-spinal pressure by the freedom with which many authors have invoked an excess of intracranial tension as the explanation of various clinical phenomena without any measurement of that pressure.

The following is a description of the instrument with an abstract of as much of the results of about 50 clinical cases as space will allow. It will be seen that the instrument is easy and safe in application and that the diagnostic and therapeutic results have often been surprisingly good. I had believed myself first in the field, but I find that Professor Krönig of Berlin has invented a more complicated instrument for the same purpose.

The instrument consists of the lumbar puncture needle, which is adapted [illegible] handle which is detachable. The three hollow needles supplied are suitable for children, large or small adults. These needles are all tempered as tough as possible, so that the risk of their breaking *in situ* is avoided. Included in the case is a hydrometer for measuring the specific gravity of small quantities of the cerebro-spinal fluid. T[illegible] the whole apparatus is [illegible] dish of boiled water. [illegible] knees drawn up and the back arched. The head and spinal column must be approximately horizontal. In uncontrollable patients it is very helpful to pass a long strap beneath the knees and round the shoulders. This arches the spine and renders struggling quite futile. In nervous patients a little cocaine beneath the skin and a little more near the bone is recommended but the pain is not great, being about equal to that of aspiration of the chest.



The skin is carefully cleansed and the needle is introduced at the level of the iliac crests half an inch below and external to a vertebral spine. The spinal cord terminates several inches above this point. The needle is pushed in with a slightly upward tilt. If bone is struck the direction must be slightly altered until the firm soft resistance of the ligamentum flavum is encountered. Once past this no further resistance is felt and the point of the needle finds itself free in the lake of cerebro-spinal fluid amongst the cauda equina. Cerebro-spinal fluid now runs up the manometer tubing (the exit tube having been previously clamped) and its pressure can be read off. Sometimes the cerebro-spinal fluid requires a little coaxing, by milking or pinching the rubber tube before it will flow into the manometer. Forcible aspiration, as by a syringe, should never be employed. Fluid can now be allowed to trickle from the exit tube by removing its clamp and clamping the manometer tube. The needle is withdrawn when the pressure is sufficiently reduced or the requisite amount of fluid has trickled out. An ounce or an ounce and a half is frequently withdrawn and usually leaves the pressure about zero. The fluid is set aside to see if it clots and is examined by the hydrometer, the microscope, or other means.

In children the operation is easy but in an average man the needle has to traverse three inches of flesh, so that one must be prepared for a little patient probing in difficult cases. Rigid asepsis is of course imperative but I have never seen any septic troubles and the fluid will keep in a test tube a surprisingly long time without obvious decomposition. The apparatus shows clearly the oscillations in cerebro-spinal pressure produced by the pulse and respirations. In fact, one has the whole central nervous system in a perfect natural bony plethysmograph.

T[illegible] to the Hull branch of the [illegible] space now only allows a selection of the more noteworthy cases.

CASE 1.—The patient was a boy, aged 13 years, who three weeks previously had been knocked on the head with a bat. For a week he lay in the hospital in a drowsy, apathetic condition, with headache, facial twitchings, and occasional vomiting. The morning after half an ounce of cerebro-spinal fluid had been withdrawn he was transformed into a bright and cheerful boy. His pressure was ten inches, which is higher than normal (from three to eight inches).

CASE 2. *Pontine* [illegible] Lumbar puncture w[illegible] only completed when the last few respirations were being taken. The pulse continued a good deal later. The fluid was *pink* and the pressure was eight and a half inches. Three drachms were withdrawn, reducing the pressure to five inches. This pressure was sustained after death with no sign of diminution after several minutes. I attribute this to the engorged condition of the venous system. The pink fluid was a valuable diagnostic guide to the apoplectic origin of the coma; this was verified post mortem.

CASE 3. *Concussion*.—The patient was a boy, aged eight years. The case was diagnosed as fractured base; the fluid, however, was colourless and the pressure was only six and a half inches, which corrected the diagnosis into *concussion*. He was much better after th[illegible]

CASE 5. *Fractured base* [illegible] patient was a man, aged 54 y[illegible] ear and nose. Lumbar puncture on the eleventh day gave a pressure of seven inches only but the fluid was slightly turbid and *clotted* on standing. This gave a diagnosis of meningitis which was only a suspicion otherwise and which was confirmed by subsequent symptoms and by post-mortem examination. On the thirteenth day the pressure appeared to rise quickly from two and a half to ten inches, owing to fright from a little pool of burning ether which was accidentally lighted near the patient's nose. He was semi-conscious at the time.

CASE 10. *Cerebral thrombosis*.—The patient was a man, aged 57 years, who for a week had been developing left hemiparesis with severe headache. Three days later he was comatose and seemed to be dying, with a slow feeble pulse. With strychnine and two lumbar punctures (three drachms each) he soon recovered consciousness and could talk in three weeks and walk in two months. His recovery seemed remarkable.

CASE 11. *Pneumonia*.—The patient was a man, aged [illegible]0 years, with intense toxæmia and violent delirium. One ounce of clear fluid was withdrawn, reducing the high pressure of from 12 to 18 inches down to three inches. No improvement followed. The high pressure in this case was doubtless due to the distended right heart and veins.

CASE 14. *Fractured vault*.—The patient was a child, aged five years. As the clot was extra-dural the cerebro-spinal fluid was not blood-stained. No benefit ensued.

---

[1] Made by Messrs. Allen and Hanburys, Limited, 48, Wigmore-street, London, W.

Case 15. *Acute tuberculous meningitis.*—The patient was a child, aged one year. Lumbar puncture was performed for vomiting and convulsions. The pressure was 13 inches and the fluid was clear. There was very marked improvement for two days. Puncture was repeated on the sixth day when the pressure had again risen to 12 inches. Improvement was now very transient. Diagnosis was verified post mortem. This was my first measurement of cerebro-spinal pressure (February, 1903).

Case 16. *Chronic hydrocephalus.*—No fluid was obtainable in this case (a child, aged three years), the cranial cavity evidently being shut off.

Case 17. *Cerebral tumour.*—The patient was a man, aged 45 years. There was a history of pains in the back of the head and neck for three months, together with vomiting and early optic neuritis. Here again, lumbar puncture yielded only a few drops of clear fluid. The pressure was not measureable even on coughing or sitting upright. The probable explanation of this is a sub-tentorial tumour pressing down the cervical medulla and cerebellum into the funnel-shaped foramen magnum. If this be the true explanation lumbar puncture gives a new and useful localising sign in this case. (Since the above was written the necropsy has shown a tumour, as large as a pigeon's egg, in the right lobe of the cerebellum.)

Case 20. *Pontine apoplexy.*—The patient was a man, aged 45 years. Here again no fluid could be obtained except a few drops at a pressure of nine inches. Post-mortem examination showed a clot in the pons as large as a walnut which had clearly corked off the cerebral from the spinal cavity. Expansion upwards was prevented by the strong tentorium cerebelli.

Case 21. *Double optic neuritis.*—The patient was a healthy boy, aged ten years. A history of one month's failing vision was obtained without any assignable cause. There were practically no headaches or vomiting. The cerebro-spinal pressure was very high, exceeding 16 inches, which was then the limit of the manometer. After one and a half drachms had been withdrawn it was still 15 inches. The boy was thoroughly at his ease during the process so I tried the effect of mental arithmetic. This first increased the pressure about an inch and then lowered it one and a half inches; grasping with both hands raised the pressure two and a half inches. As usual in a high-pressure case, the oscillation of the pulse was well marked and the respiratory wave was scarcely seen. 11 drachms of fluid were withdrawn, reducing the pressure to four and a half inches. The puncture was repeated in ten days when the pressure was two inches and only half a drachm of fluid could be withdrawn. The punctures appeared to have no effect on the steady downward progress of his vision. He vomited six and 18 hours after the puncture and had a trifling headache. Nine months later the father told me that the boy was well and cheerful but had nocturnal incontinence and slightly impaired memory. He could see a man 200 yards away and his vision was better after an aperient. This case suggests the possibility of disease of cerebro-spinal high tension analogous to glaucoma in the ocular cavity.

Case 22. *Fractured base.*—The patient was a man, aged 76 years. It was a severe and undoubted case. The pressure was four and a quarter inches. The fluid was pink. Recovery was complete.

Case 23. *Fractured base.*—The patient, aged 19 years, was comatose. The pressure was from 10 to 13 inches and was reduced to five by withdrawing one and a half ounces of *pink* fluid, after which the pulse was less turbulent. Recovery was rapid and complete.

Case 24. *Severe chorea.*—The patient was aged 22 years. There was decided benefit from the puncture. The pressure was normal.

Case 25. *Concussion.*—The patient was aged eight years. Vomiting, teeth-grinding, twitching, and speechlessness were present. Complete recovery followed a few hours after puncture (one drachm) The pressure was normal.

Case 26. *Tuberculous meningitis.*—The pressure was 19½ inches. The child slept well after puncture—a common result. Improvement was transient.

Case 27. *Uræmic convulsions with total blindness.*—The patient was a middle-aged man. The convulsions were relieved by venesection but the coma remained. Lumbar puncture under chloroform was performed by Dr. Carter. The pressure was high (16½ inches). On the next morning the man was quite conscious and had recovered much of his eyesight. Dr. W. C. Rockliffe, our ophthalmic surgeon, examined the eyes and found very marked optic neuritis. He was much impressed by the extent and rapidity of the recovery of vision. A second puncture produced no further increase of vision.

Case 28. *Anomalous cerebellar ataxia.*—The patient was a man, aged 35 years, with a history of pain, numbness, and feeble gait for six years, and a strong family history of adolescent paralysis. The diagnosis was obscure. Extraordinary improvement followed after withdrawing one ounce of fluid at normal pressure, suggesting functional disease. He was at work six months later, quite well.

Case 29. *Acute tuberculous meningitis.*—The patient was a child, aged seven years, who three months previously I had seen operated on for undoubted tuberculous peritonitis. The child was admitted for acute periostitis of the ankle. No pus was found on incision. Five days later the child had a severe clonic convulsion lasting for two hours, preceded by several days of irritability and sulkiness. The fit ceased 15 minutes after lumbar puncture, which showed a pressure of 15½ inches. Four days later, vision, which apparently had been totally lost since about the time of the fit, was returning. Five months later the mother tells me the child's health is normal in every respect. I have to thank Mr. G. A. Carter for a careful report of this striking case which occurred in my absence.

Negative cases.—The cases where lumbar puncture produced little or no result included Ménière's disease (severe and senile case), alcoholic neuritis and myelitis, neurasthenia, miliary tuberculosis, chronic headache, and gastric tabetic crises. The amount of fluid withdrawn was usually between half an ounce and one and a half ounces and the pressure varied between zero and 18 inches of water.

Conclusions.—The following points appear to be suggested by the above cases:—

1. The therapeutic effect of lumbar puncture is, I think, often greater than it is given credit for. This is difficult to prove or to explain (and hence to believe) but the following may be factors: (*a*) excessive tension is reduced; (*b*) the brain is washed by fresh fluid secreted in place of that withdrawn; (*c*) a temporary cerebral hyperæmia is produced by the blood-vessels dilating to take the room of the fluid withdrawn until a new supply is secreted, or, conversely, a cerebral anæmia due to excessive intracranial pressure may be arrested; and (*d*) a substantial *change* of cerebral environment is produced of which nature may sometimes be able to take advantage.

2. Lumbar puncture has been performed about 60 times with this instrument without any ill-effects, so that the risk is not great, and the further exploration of this therapeutic field is justified.

3. Valuable diagnostic information is often afforded. (*a*) Pink fluid indicates cerebral hæmorrhage, fractured skull (with injury to the dura mater), or severe superficial cerebral laceration (with rupture of the pia mater). Except for the first few drops the fluid is very seldom blood-stained from trauma by the needle with this instrument. (*b*) A faint "spider's web" clot after standing several hours points strongly to meningitis. (*c*) Cytological, bacteriological, or inoculation experiments may give the diagnosis. (*d*) Occlusion of the cerebral from the spinal cavities may be diagnosed (see Cases 16, 17, 20) and this may localise a sub-tentorial tumour (Case 17).

4. In apoplexy, lumbar puncture is conceivably justifiable when the pressure is found to be very high, provided that the pressure is slowly reduced to half its value, not too soon after the occurrence of the hæmorrhage. But if this treatment should be found to be justifiable with a manometer, it would certainly be dangerous without one.

5. Case 12 suggests the possible existence of a disease in the cerebro-spinal cavity analogous to glaucoma in the ocular cavity—that is, a disease of high pressure due to obstructed outflow of secretion. There are many cases of neuritis and atrophy of the optic nerve which still require an explanation.

6. Lumbar puncture is said to be dangerous in cerebral tumour. The sitting-up position advised by some French and German authorities has serious theoretical risks.

7. Credit for therapeutic effects is hard to allocate, but surprisingly good results followed lumbar puncture in fractured base (Cases 22, 23), concussion (Cases 3, 25), post-traumatic cerebral condition (Case 1), cerebral thrombosis (Case 10), very severe chorea (Case 24), uræmic coma and

optic neuritis (Case 2), anomalous ataxia case (Case 28), and tuberculous meningitis (very early stage) (Case 29).

8. Hence, I think that lumbar puncture should be tried as a therapeutic effort in a variety of cerebral conditions which are not hopeless but which are stationary or retrocedent under ordinary treatment. Also that the cerebro-spinal pressure should be measured in every case of lumbar puncture for the present.

This investigation would have been impossible without the kindness of the honorary and resident staff of the Hull Royal Infirmary. My sincere thanks are therefore due to Dr. G. F. Elliott, Dr. Frank Nicholson, Dr. E. O. Daly, Mr. E. H. Howlett, Dr. D. Lowson, Dr. Rockliffe, Mr. E. Harrison, Mr. A. G. Francis, Mr. Guy B. Nicholson, and Mr. Carter; also to Sir Victor Horsley.

CLINICAL SOCIETY OF LONDON.

Malarial Affection of a Joint.—Intermittent Hydrops of the Joints.—Hydronephrosis due to Moveable Kidney.

A MEETING of this society was held on April 14th, Dr. FREDERICK TAYLOR, the President, being in the chair.

Professor HOWARD MARSH communicated a case of Affection of a Joint possibly due to Malaria. The patient was a man aged 38 years, in whom there was a history of syphilis and who had lived abroad and contracted malaria. In April, 1903, his knee became the seat of severe pain but without swelling or loss of movement. When first seen in December, 1903, the joint appeared natural but the muscles were very much wasted and were so weak that he was unable to raise his heel from the bed. He complained of agonising pain from his hip to his ankle. Every evening the joint became considerably swollen and measured one and a half inches more than the other, the swelling having a remarkably globular appearance. There was no fluid in the joint and the swelling seemed due to vascular turgescence of the synovial membrane. The patient stated that the joint swelled up in this manner every evening and then gradually returned to its natural size. After the administration of quinine in ten-grain doses twice a day for four days the attacks of swelling had disappeared and the patient recovered muscular power in the limb so rapidly that in three weeks he was able to walk three or four miles without any bad result. Six months later he had a patch of swelling covered by overwa [illegible] ernal malleolus, [illegible] d by quinine. [illegible] and no parasites were found, but on account of the periodicity of the swelling of the knee recurring at intervals of 24 hours, and that it was attended with severe neuralgic pain and relieved by quinine, Professor Marsh believed it was possible that these symptoms were due to malaria and referred to the "brow ague," neuralgiæ, and other symptoms occurring in malarial subjects.—Sir PATRICK MANSON remarked that Professor Marsh's case had again raised a question which had been often discussed but never settled—namely, [illegible] and, secondly, as a condition due to the lowered vitality caused by the malaria. Thus syphilitic or other poisons produced a greater effect in a person who had had malaria [illegible] see [illegible] due [illegible] ch was common to many con- [illegible] septic fevers. In malaria the [illegible] tertian or quartan. Moreover, in this case the exacerbation of symptoms had been in the evening, which was a common event in syphilis but rare in malaria; the typical feature of malarial symptoms was their occurrence before midday. There were no other manifestations of malaria, such as fever and enlargement of the spleen. He paid less attention to the absence of the malarial parasite from the blood, for quinine had been previously administered; it would have been more useful to examine the blood before this administration. He would like to know how recently the patient had been exposed to malarial infection, for in his experience no active evidences of malaria ever occurred after three years at the utmost from such possible infection. He referred to various conditions that had been termed irregular malaria, notably periodic nervous, cutaneous, and gastric symptoms. He did not know of any that had had the two great malarial tests applied to them—namely, finding of the parasite and observance of the malarial periodicity, though he referred to two cases of urticaria which were probably malarial on account of their clinical features. The malarial parasite undoubtedly had a predilection for certain organs but he doubted if the joints should be included among them.—Lieutenant Colonel T. R. MULRONEY, I.M.S., had seen many cases of malaria complicated by syphilis, the manifestations of which were more decided than in non-malarious subjects and were [illegible] of potassiu [illegible] a case wh [illegible] Professor M [illegible] elapsed since the man had been abroad.

Professor MARSH also made a communication on three cases of Intermittent Hydrops of the Joints occurring in a woman aged 28 years, a man aged 42 years, and a boy aged 12 years. These three cases were in all their essential features very similar to each other. The effusion in the joints returned with remarkable periodicity: in two every 14 days and in one every 12 days. In all the local condition—mere increase of synovial fluid—was the same. In all, the joints in the intervals seemed normal. These cases were typical instances of the usual form of intermittent hydrops of the joints and they closely resembled those which were observed or recorded by Dr. E. J. Brackett and Dr. F. I. Cotton.[1] In these examples the periodicity was always marked but the interval between the attacks varied in different individuals from three or four days to 30 days or more, the most frequent interval being 14 days. In several instances the attacks continued for three, four, or even more years. Some cases after showing definite periodicity lost this feature and the attacks became irregular both as to the time of their recurrence and their severity. The pathology of this affection was not known. It might be that under the influence of some ca [illegible] disturbance led to synov [illegible] In regard to treatment, [illegible] appeared to be useful. [illegible] ing on their own accoun [illegible] errors in practice, for [illegible] well suggest the presenc [illegible] fringe for which a useless operation might be performed.—Mr. F. O. WALLIS expressed the belief that such cases as those now described by Professor Marsh were due to some micro organism or its toxin and thought it would be interesting to know the results of a series of cultures taken from the fluid in the joint. He had opened and washed out the affected joint in one case with advantage.—Dr. F. J. POYNTON pointed out that micro-organisms in affections of the joints were commonly confined to the subendothelial layer and were rarely found in the fluid. He was not of opinion that the cases described were of microbic origin but rather of the nature of an œdema or an urticaria. It was, however, well known that the subcutaneous injection of certain toxic and antitoxic sera, such as those of diphtheria and tetanus, could produce synovial effusion. Had urticarial or erythematous lesions been observed in Professor Marsh's cases.—Dr. F. W. FORBES-ROSS thought that the effusion was probably a serous hæmorrhage into the joint, due to a diminution in the coagulability of the blood. Malaria was known to predispose to this condition and œdema often occurred in such subjects after the administration of mercury.—The PRESIDENT asked on what grounds arsenic had been given.—Professor MARSH said that those who had seen many of these cases recommended arsenic but some cases did not improve with it, whereas most cases spontaneously improved. He did not think that the condition was of infective origin, for there was no structural alteration of the joints, even after repeated attacks. He had not examined the synovial fluid or the blood in his cases. Dr. A. E. Garrod had told him of three cases which he had seen, two of which were the direct sequelæ of gonorrhœal rheumatism.

Mr. F. J. STEWARD communicated two cases of Hydronephrosis due to Moveable Kidney. These two cases were brought forward on account of the marked degree of hydronephrosis caused solely by the undue mobility of the kidney which resulted in the formation of a sharp kink in the upper part of the ureter, as described by Gigon in 1856. The first case was that of a young woman, aged 20 years, who had had attacks of pain in the right loin for eight weeks before admission to Guy's Hospital in February, 1900. A large, freely moveable, fluctuating tumour was found in the right loin. The tumour varied somewhat in tenseness but never disappeared, the pain being worse when the tumour was most tense. The tumour was explored through a lumbar incision and found to be a large hydronephrosis caused by a sharp bend in the upper part of the ureter which was easily straightened out by pushing the kidney up into its normal position. The kidney was fixed by silk sutures to the parietes and the wound was closed. The patient had no further pain and the average daily excretion of urea increased from 167 grains to 277 grains. On examination nine months later the tumour was found to be markedly smaller but it had not disappeared. The second case was that of a girl, aged 18 years, who was admitted into Guy's Hospital 16 weeks after a right-sided hydronephrosis had been opened and drained. The cause of the condition was found, as in Case 1, to be a kink of the upper part of the ureter which was straightened out by pushing the kidney upwards. The kidney and the upper part of the ureter were fixed to the parietes and a catheter was passed down the ureter from the old drainage opening in the convex border of the kidney. Six months later there was no return of the hydronephrosis and the kidney remained firmly fixed in its normal position.—Mr. R. Clement Lucas referred to four cases which he had recorded at the meeting of the British Medical Association in 1891, in all of which a moveable kidney had terminated in hydronephrosis. In all there had been intermittent attacks of very severe pain from time to time and these symptoms indicated a kinking and blocking of the ureter. Sometimes the conditions could be cured by fixing the kidney in its proper position but in one case he had watched the gradual destruction of the kidney. In another case the condition was cured for some years by a pregnancy but some years later considerable trouble arose from the formation of pyonephrosis. The kidney often became fixed in the wrong situation, with the result that recurrence took place.—Mr. William Turner related the details of a similar case on which he had operated recently. He speculated as to the mode of infection that converted a hydronephrosis into a pyonephrosis.—Dr. Forbes-Ross pointed out the importance of the direction in which the kidney subsequently shrank. As they could not foretell this direction would it not be better to examine the opposite kidney by laparotomy and then remove the hydronephrotic kidney if the other was healthy?—Mr. Steward replied.

LIVERPOOL MEDICAL INSTITUTION.

Aspiration of the Chest.—Paramyoclonus Multiplex.—Hæmorrhage due to High Arterial Tension.—Floating Kidney.—Prognosis in Pulmonary Tuberculosis.

A meeting of this society was held on April 13th, Dr. James Barr, the President, being in the chair.

Dr. William Williams demonstrated an improved method of Aspiration of the Chest.

Dr. J. C. M. Given related a case of Paramyoclonus Multiplex occurring in a man, aged 21 years. The contractions were unilateral in distribution, affecting mainly the muscles of the forearm, the leg, and the abdomen on the left side. The patient's mother had suffered from chorea gravidarum whilst pregnant with this child. He had had two severe accidents at long intervals to which he attributed the commencement and the increase of the disease. The administration of $\frac{1}{100}$th of a grain of hyoscine hydrobromate twice daily had been followed by distinct improvement.—The President, Dr. T. R. Glynn, and Mr. R. C. Dun discussed the case.

Dr. A C Wilson related five cases of Hæmorrhage apparently due to High Arterial Tension. Case 1 was that of a youth, 20 years of age, who from early childhood had been subject to bleedings from the nose. During one week he had two severe attacks of hæmatemesis. The radial pulse denoted high arterial tension and there was no pain or tenderness over the epigastrium suggestive of gastric ulcer. The patient quickly improved on taking large doses of perchloride of iron. Case 2 was that of an elderly woman the subject of arterio-sclerosis. She was suddenly seized with dizziness and her congested face and slow high-tension pulse threatened an attack of apoplexy. Fortunately this was averted by profuse bleeding from the nose. Case 3 was one of cerebral hæmorrhage which occurred in a man, 38 years of age. There were aphasia and paralysis of the right side. He gradually made a complete recovery. Case 4 was that of a female, 45 years of age, who for the last 17 years had had attacks of hæmoptysis, at one time thought to be due to pulmonary tuberculosis. Her general health was excellent; the sputum did not contain tubercle bacilli. Case 5 also was a case of hæmoptysis. The patient, a man, 48 years of age, had for six years been subject to slight attacks of bleeding. There were no physical signs of pulmonary tuberculosis and the sputum did not contain tubercle bacilli.—The cases were discussed by Dr. Given, Mr. Rushton Parker, Dr. Glynn, and Dr. John Hay.

Dr. Charles Pinkerton related a case of Floating Kidney in which the symptoms closely resembled those due to gall-stones. The patient was a married woman, 38 years of age, who during the last 18 months had 12 attacks of great pain in the right side with sickness followed by jaundice. She had lost four stones in weight during that time. Physical examination revealed a floating kidney and a dilated stomach. A belt for the kidney was ordered but before it arrived she had another attack, a typical Dietl's crisis, attended, however, by jaundice. After wearing the belt she rapidly gained in health and weight and had remained perfectly free from all attacks since.—Dr. T. R. Bradshaw referred to a case the converse of this in which a woman had a freely moveable kidney and hepatic pains but an operation for the removal of gall-stones completely cured her.

Dr. R. J. M. Buchanan read a paper on the Prognosis in Pulmonary Tuberculosis. The pulmonary infection was peculiar, affecting as it did organs which lent themselves, by structure, vascularity, mobility, and communication with the exterior, to easy dissemination and secondary infections. The difficulties of prognosis were very great and the clinical course of the disease was full of surprises. It was pointed out how dangerous it was to relate closely the pathological and clinical stages in forming a prognosis and reference was made to the post-mortem proofs of the spontaneous curability of pulmonary tuberculosis. The question of predisposition, acquired or hereditary, was discussed. In reference to the latter it was considered that evidence was gradually accruing in support of a less gloomy view being taken of the prognosis in such cases and that an inherited predisposition was general rather than specific to tubercle. The value of physical signs was fully considered—cough, hæmoptysis, mixed infections, and complications. The value of constitutional symptoms as prognostic factors was discussed at length, with special reference to the temperature, nutrition, and circulation. In reference to the duration and course of the disease difficulties arose in obtaining the exact date of incidence. In conclusion, he advocated that the prognosis in pulmonary tuberculosis should be based upon a careful study and estimation of (1) the general constitutional condition of the patient; (2) the effects of the disease upon the body temperature, nutrition, and circulation; (3) a recognition of the extent of the lung involved and the ability of that left to carry on the respiratory process; and he said (4) that the above were the important factors and in comparison with them physical signs as they interpreted local pathological "stages" of the morbid process occupied a subordinate position. Valuable as might be their diagnostic importance they formed an untrustworthy basis for prognosis.—Dr. Nathan Raw said that the virulence of the infection and the resisting power of the tissues decided the fate of the person attacked. A predisposition to tuberculosis often made the prognosis unfavourable. Treatment commenced early and maintained under proper surroundings would of course favour arrest of the disease.—Dr. Hay said that an opinion based upon the physical signs always under-estimated the extent of the lesion. In forming an opinion as to the prognosis due consideration should always be given to the result of previous treatment.—Dr. W. B. Warrington, Dr. J. Hill Abram, Dr. Wilson, Mr. W. B. Bennett, and Mr. O. Bowen also took part in the discussion.

Forfarshire Medical Association.—A meeting of this society was held on April 7th in the School of Medicine, Dundee, Dr. James Orr (Tayport) being in the chair.—Dr. R. C. Buist read notes on three cases of Icterus Gravis or Grave Jaundice—terms which he used as meaning severe jaundice associated with unconsciousness The first patient was a woman who was at that time in the seventh month of her fifth pregnancy and who in a previous pregnancy had a transitory jaundice On admission to hospital she was in a state of coma and collapse, suffering from very marked jaundice vomiting, constipation, petechial hæmorrhages, and all the other symptoms described in acute yellow atrophy of the liver The liver dulness was greatly diminished, there was no leucin or tyrosin in the urine Two pints of normal saline solution were introduced into the left breast and five ounces of saline solution were given every two hours per rectum Calomel and mistura alba were given by the mouth After 24 hours, the bowels being still unmoved, a large soap and water enema was given, which proved effectual The saline enemata were continued for several days Under this treatment, in spite of the onset of premature labour, the patient made a complete recovery The second patient was a woman who with catarrhal jaundice of a few days' standing suddenly became unconscious and delirious The bowels were found to be overloaded and a sharp purge was quickly followed by recovery with no bad symptoms The third patient was also a woman who, while suffering from jaundice, suddenly developed grave symptoms similar to the first case No leucin or tyrosin was found in the urine Death took place on the seventh day after the onset of bad symptoms On post mortem examination the liver was found to be very small and shrunken, very soft and flabby, showing on the surface and section orange yellow patches The condition was without doubt one of acute yellow atrophy of the liver The chief point for consideration was, Could the first case be called one of that disease also and if so could the favourable ending be the result of the treatment? Dr Buist considered that both answers must be *in the affirmative* The condition being one of toxæmia the rational treatment was to dilute the toxin as much as possible and this was accomplished by the saline injections He mentioned that he could not agree with the usual statement that acute yellow atrophy was most common in pregnant women, he considered that both sexes were equally liable to be attacked by the disease and that early adult life was the commonest age —Professor J A C Kynoch who had seen the first case agreed that it was one of acute yellow atrophy —Dr J Mackie Whyte, Dr D M Greig, Dr W E Foggie, and others also took part in the discussion —Professor Kynoch read a paper entitled "A Retrospect of 100 Gynæcological Laparotomies' The cases were tabulated as follows ovariotomy, 54, extra uterine gestation, 10, fibromyomata, 11, tubal disease, seven, oophorectomy, seven, ventro fixation of prolapse three, *exploratory* operations, four, ventral hernia, two, and Cæsarean section, two Among these 100 cases there were nine deaths

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY —A meeting of this society was held on April 14th, Dr D Lloyd Roberts being in the chair —Dr J B Hellier (Leeds) narrated a case of Hæmorrhage into a Small Ovarian Cyst accompanied by flooding of 12 days duration during an inter menstrual period in a young unmarried patient —Dr G W Fitzgerald (Manchester) showed a Hæmatoma of the Broad Ligament which *occurred* in connexion with torsion of the Fallopian tube in a woman, aged 42 years, who had ceased to menstruate for some months —Dr W K Walls (Manchester) showed Three Uteri removed by Vaginal Hysterectomy for Cancer of the Body The indications for operation were hæmorrhage after the menopause, accompanied by enlargement of the corpus uteri It was possible to curette in these cases without finding any evidence of malignant disease and bleeding with enlargement after the menopause was sufficient to justify removal of the uterus —Dr F B Grimsdale (Liverpool) related a case of Intraperitoneal Rupture of the Bladder during the first stage of labour in a primipara A portion of the fundus of the bladder sloughed and on opening the abdomen a gallon of urine was removed from the peritoneal cavity The bruised portion of bladder, which was perforated in the centre, was excised and the wound was closed with fine silk The patient made an easy recovery —Dr A J Wallace (Liverpool) read a paper on Removal of the Cancerous Cervix by the Abdominal Route with Pelvic Dissection based on an experience of ten cases Beginning with the purely abdominal route he had been led to employ the combined operation in preference The uterus, adnexa, pelvic connective tissue, and glands were first freed by laparotomy and then extracted per vaginam Details of the ten cases were given Three operations were incomplete Out of the ten cases the iliac glands were cancerous in three and the right obturator gland in another In two cases the glands were diseased although the primary lesion was in an early stage The uterus being freely moveable and all signs of infiltration being absent, Dr Wallace considered that in properly selected cases the combined operation promised better chances of success than those afforded by the vaginal route —Sir W J Sinclair condemned the operation on the ground that cases which could not be dealt with by vaginal hysterectomy aided, if necessary, by paravaginal incision were not suitable for operative treatment at all The mortality of the operation under consideration was very high and many of the patients who recovered continued to suffer through urinary fistula —Dr H Briggs had not performed the operation He considered that any advance in operative technique should be made strictly on the lines of progress in general surgery —Dr A W W Lea pointed out that Sir W Sinclair was in the habit of treating by vaginal hysterectomy many cases of cervical carcinoma which would be regarded as inoperable by most gynæcologists

LARYNGOLOGICAL SOCIETY OF LONDON —A meeting of this society was held on April 7th under the presidency of Mr Charters J Symonds The following cases and specimens were shown —Dr H J Davis a case of (?) Traumatic Perforation of the Nasal Septum in a boy, aged 17 years, who was engaged in flour mills Epistaxis had followed the injury He also showed a piece of Blue Chalk, half an inch long, which had remained for three weeks impacted in the respiratory passage of a boy, aged 10 years Dyspnœa and bronchitis had supervened The chalk was dislodged and swallowed during laryngoscopic examination and was passed per rectum —Dr W Jobson Horne showed a case of Malignant Disease of the Larynx —Dr W H Kelson exhibited a case of Lingual Growth in a man aged 45 years Some doubt was expressed as to whether this was a papilloma or a thyro lingual cyst —Mr H L Lack exhibited a case of Deformity of the Hard Palate and Teeth due to nasal obstruction in a boy with facial paralysis, showing the factors in the causation of high arched palate —Dr L H Pegler showed a case of Broadening of the External Nose caused by tense symmetrical swellings attached to the cartilaginous septum He also exhibited an Obstinate Crusting and Pus Formation in a man, aged 40 years, shown for diagnosis Both turbinals had been removed —Mr Robinson showed a case of Angio fibroma of the Vocal Cord —The President exhibited a very interesting case of Angioma of the Larynx in a man, aged 34 years He also showed a woman aged 52 years, in whom the Larynx and Thyroid Gland had been Extirpated for Cancer, and also a case of Papilloma of the Larynx in a man, aged 30 years —Mr E B Wiggett showed a case of [illegible] Empyema cured by operation, and Dr H Tilley [illegible] was that of a woman, aged 31 [illegible] causing stenosis of the [illegible] It was thought to [illegible] econd case (one for diagnosis) was in a man, aged 64 years, with Recurrent Paralysis of the Right Vocal Cord and some difficulty in swallowing The right pupil was contracted and there were slight ptosis of the eyelid and wasting of the upper part of the right trapezius It was considered by some of the members present that the cause of the trouble was peripheral and not central —Dr J Donelan showed a man, aged 39 years with Lateral Ulceration of the Larynx There had been hoarseness for about two months but there was no history of syphilis

---

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN —A quarterly court of the directors of the above society was held at 11, Chandos street, London, W, on April 12th, Mr Christopher Heath, the President, being in the chair Three new members were elected The treasurer announced that a legacy of £250, duty free, had been received from the executors of the late Mrs Jane Begley One new widow and one orphan were granted relief at the rates of £50 and £12 per annum respectively The sum of £1293 had been paid in half-yearly grants in January to the annuitants of the charity 53 widows and 17 orphans are now on the books of the society The date of the annual general meeting was fixed for Monday, May 22nd, at 5 P M, at the offices of the society.

Reviews and Notices of Books.

International Clinics. Vol. II. Fourteenth Series, 1904. Edited by A. O. J. KELLY, A.M., M.D., Philadelphia, U.S.A. London: J. B. Lippincott Co. 1904. Pp. 314.

THIS volume maintains the high standard of excellence which has characterised its predecessors. The first portion of the book is occupied with a series of communications on Diseases of Warm Climates. The first article is by Dr. C. F. Mason and is entitled "The Spread of Diseases by Insects, with Suggestions regarding Prophylaxis." The science of preventive medicine has made great advances during recent years and in no department have more far-reaching results been obtained than in the demonstration of the important part borne by certain insect pests in the spread of disease. Dr. Mason asserts that at the present time insects are known to spread the following diseases: yellow fever, malarial fever, filariasis, spotted fever, sleeping sickness, dengue, anthrax, cholera, plague, dysentery, epidemic diarrhœa, and tuberculosis. The part that insects play in disseminating the above diseases is fully recognised with regard to some of them, whilst in the case of others absolute proof is not yet forthcoming. The insects the culpability of which as carriers of disease has been established are the mosquito, the house-fly, the nagana or tsetse fly, and ticks, while fleas, lice, and especially bed-bugs are under strong suspicion. The fact that certain diseases require for continued existence the presence of a particular insect explains the geographical distribution and the seasonal prevalence of these diseases, which must be the same as those of the insect carriers. Dr. Mason draws attention to the important difference that exists in the action of the mosquito as an intermediate host in the case of yellow fever and malarial fever respectively. In the former the mosquito appears to be the permanent, and the human body the temporary, host of the pathogenic parasite; the disease lasts only a few days and is followed by immunity to further attacks. In malarial fever the patient is the permanent host and having once been infected may harbour the disease for years, and outbreaks may therefore occur outside the geographic range of the mosquito. These facts merit more notice than they have hitherto received. Dr. Mason's remarks on prophylaxis are also interesting. He mentions the results that have been obtained by the sanitary department in Havana since efforts have been made devoted to the extermination of the yellow fever mosquito. For more than two years no case of yellow fever has originated in Cuba and though the disease has repeatedly been brought there from other infected points it has not spread. Previously Cuba had not been free from yellow fever for about 150 years.

Amongst other articles in this section the following may be mentioned: Recent Progress in Tropical Medicine, by Dr. John McCrae; Sleeping Sickness, by Dr. C. Jarvis; and Liver Abscess and its Treatment, by Mr. James Cantlie. The article on Uncinariasis (ankylostomiasis) also contains a large amount of information concerning the genus uncinaria. The pathology, the symptomatology, and the treatment of the disease in human beings are also carefully considered.

In the section on Treatment will be found some contributions on the therapeutics of diseases of the cardiovascular system. Dr. J. B. Nichols (Washington) writes on the Etiology, Diagnosis, and Treatment of Arteriosclerosis. Dr. Nichols believes that physicians are apt to look upon the condition of arterio-sclerosis in a rather academic manner and that they often fail to realise the very important and practical influence which it exerts upon the system and the organs of the body. We cannot agree with this remark, for since the writings of Sir William Gull, Dr. H. Gawen Sutton, and others, general attention has always been given to the significance of hardened arteries and increased blood pressure. Dr. Nichols's remarks in general, however, are well worthy of perusal and study.

Amongst the other contributions to this volume we may mention the following: Osteomalacia, by Dr. George E. Malsbary; Intestinal Obstruction in Children, by Dr. C. J. Cumston; and Subparietal Injuries of the Kidney, by Dr. Miles F. Porter. We can recommend this volume as a most interesting one and as a valuable addition to the already extensive series of "International Clinics."

The Nervous Affections of the Heart. By GEORGE ALEXANDER GIBSON, M.D., D.Sc. Edin., F.R.C.P. Edin. London and Edinburgh: Young J. Pentland. 1904. Pp. 99.

THIS volume comprises the Morison lectures delivered before the Royal College of Physicians of Edinburgh in 1902 and 1903 and they are now reprinted from the *Edinburgh Medical Journal*, in which they were originally published. The first section consists of three lectures dealing with sensory disturbances of the heart from the clinical, pathological, and therapeutical aspects; the second section similarly is concerned with motor disturbances; and three lectures deal respectively with rate, rhythm, and force. The first lecture is prefaced by a very entertaining historical sketch of the various steps by which our present knowledge has been gained; this indicates a wide range of interesting reading, together with some happy guesses at the nature of the maladies of sundry distinguished persons. Dr. Gibson mildly rebukes Dr. Huchard for an attempt to associate the name of Rougnon with angina pectoris and objects to Professor Osler's recognition of the two varieties of true and false angina. The description of the phenomena of an attack of cardiac pain is written with considerable vivacity and due regard is paid to the alteration in the skin, the disturbance of digestion, and the modifications of the renal secretion. The lecture on pathology is mainly occupied with an account of the innervation of the heart, the description being materially assisted by numerous diagrams. Dr. Gibson speaks very enthusiastically of the results of therapeutic measures. He fearlessly asserts that "in not a few of the worst cases, even when death seems to stare the patient in the face, judicious treatment brings about recovery which may for several years remain unimpaired." The general line of treatment here advocated does not present any novelty although it will probably be useful to refer to it from time to time. With the second section upon motor disturbances we are once more entertained with references to the literature connected with the movements of the heart. The author in turn cites Homer, Lucretius, Horace, Isaiah, and Shakespeare. After a brief rest he refers to Aristotle, Herophilus, Rufus of Ephesus, Galen, and William Harvey; then there is another pause before we are hurried on to Laennec, Walshe, and Stokes. The subject of the lecture is then approached more seriously and bradycardia and tachycardia are considered. The two concluding lectures on rhythm and force are full of light entertainment as well as instruction. Dr. Gibson ranges far and wide in search of apposite illustrations and he does not lose sight of the main object of a lecturer, the judicious selection of a flavouring agent to make the mixture palatable. Of the influence of tobacco upon cardiac rhythm he says: "Certain forms of tobacco are almost innocuous, others are pestilential in the highest degree; and some of the tobaccos that have obtained a very great vogue on account of the literary romance thrown around them are without doubt the most deleterious of the whole series." These broad terms are not very helpful but the Scylla and Charybdis of a medical lecturer may be represented by professional etiquette, on the one hand, which forbids advertisement, and the legal aspect, on the other, which checks libellous identification, and between these two the lecturer must steer with difficulty and anxiety.

Transactions of the Ophthalmological Society of the United Kingdom. Vol. XXIV. Session 1903-04. London: J. and A. Churchill. 1904. Pp. li.—386. Price 12*s.* 6*d.* net.

THIS well-arranged work recording the Transactions of the British Ophthalmological Society during the last session contains many papers of interest. The presidential address delivered by Mr. John Tweedy dealt with the Relation of Ophthalmology to General Medicine and Surgery and to Public Health. He pointed out that there is a disposition amongst ophthalmologists to specialise to too great an extent, to split this branch of medicine into two departments—the optical and the medico-surgical—which tendency should be strongly resisted on the ground that "no one can safely and intelligently deal even with the optical defects of the eye unless he has an adequate knowledge not merely of the structure and diseases of the eye but of the varied relations of the eye to the whole organism." The book is arranged in a topographical manner, so that those who are interested in the cornea, the retina, or the orbit can turn to that section and read all the cases that have relation to it which have been brought before the society in the course of the year. Many rare forms of disease are here recorded which will certainly assume importance when collected and compared with others, and a knowledge of which it is one of the principal objects of the society to diffuse amongst its members. For example, a case is recorded by Mr. E. Nettleship bearing upon Mr. William Anderson's case of pemphigus of the conjunctiva presented at a previous meeting and offering some remarkable features, the vesicles appearing with extraordinary rapidity, so that, as the relatives stated, "we could see them come up in a minute or two, those in the mouth generally coming at dinner, whilst he once nearly choked from a large one that formed in the throat." Such details in affections that are rare or that are obscure in origin often complete the picture of the disease and prove of high value. The same observations apply to various cases here recorded of peculiar diseases of the cornea and to cases of congenital anterior staphyloma, in one of which a very careful examination was made by Mr. E. Treacher Collins, leading him to believe it to be due either to intra-uterine transmission of infection, which he thinks highly improbable, or to maldevelopment or, as is most likely, to intra-uterine inflammation. There is a note on Vascular Changes in the Retina by Mr. R. Marcus Gunn, which led to an interesting discussion in which Mr. R. W. Doyne, Mr. W. A. Frost, Mr. Nettleship, and the late Mr. A. Q. Silcock took part, the question at issue being the existence of ophthalmoscopic evidence of actual retardation in the venous flow where an artery crosses over a vein.

A subject of considerable general interest was brought under the notice of the society in a paper read at the close of the year by Dr. A. Freeland Fergus, having the title of "Average Visual Acuteness." In this communication Dr. Fergus points out that uniformity of illumination of the object is of much importance, whilst it is often neglected. Then, in regard to normal visual acuteness, while Snellen's types are well adapted for testing the visual acuteness, numerous cases are met with in practice in which the subject is unable to read $\frac{6}{6}$; whilst in view of the provisions of the Workmen's Compensation Act and of medico-legal inquiries and the frequency with which work is carried on after injury to one eye without loss of wages, it would be advisable, in order that just compensation should be given, to form a committee to determine as far as possible what vision is required for various avocations in life.

Mr. N. Bishop Harman has an interesting paper on the judgment of the size and the distance of objects, which he shows to be due not so much to any effort of accommodation but to the appreciation of the muscular effort in effecting convergence. Dr. W. M. Beaumont gives a note on the Eye Symptoms associated with Rheumatoid Arthritis, with especial reference to the field of vision, and there is a good article on Trichiasis and the Operations for its Relief by Mr. W. E. Cant. There are several good plates and many illustrations in the text. The volume also contains a report on Sight-testing by Spectacle Makers and a preliminary report of the colour vision committee.

Progressive Medicine: A Quarterly Digest of Advances, Discoveries, and Improvements in the Medical and Surgical Sciences. Edited by HOBART AMORY HARE, M.D., assisted by H. R. M. LANDIS, M.D. Vol. III. London: Rebman, Limited. 1904. Pp. 284. Price 12*s.* net.

THIS volume is composed of four sections by different writers. The first deals with Diseases of the Thorax and its Viscera, including the heart, the lungs, and the blood-vessels, and is contributed by Dr. William Ewart; the second is upon Dermatology and Syphilis, by Dr. William S. Gottheil; the third is on Diseases of the Nervous System, by Dr. William G. Spiller; and the last treats of Obstetrics and is contributed by Dr. Richard C. Norris. The wide range of reading necessitated for the purposes of this digest is sufficiently demonstrated by the foot-notes which give the references to the original papers. Dr. Ewart appears to have been hampered by an excessive amount of material and his account is almost too condensed to serve as much more than an indication of the sources whence instructive information may perhaps be obtained, but for this purpose it will be of great assistance to those who desire to follow the progress of recent literature. The section on dermatology has numerous illustrations from the author's cases and his account presents a running commentary in which we find details of his observations, his cases, and his treatment, in addition to the digest of recent literature. The sections upon the nervous system and on obstetrics are written with greater freedom from the personal equation and in greater detail and are accordingly likely to be of greater service to those who are unable to obtain access to the original papers. As a whole this volume is certain to save much time for all who wish to study the subjects with which it deals.

LIBRARY TABLE.

Atlas and Epitome of Operative Gynecology. By Dr. OSKAR SCHAEFFER. Authorised translation from the German with editorial notes and additions. Edited by Professor J. CLARENCE WEBSTER. With 42 coloured lithographic plates and many illustrations in the text, some in colours. London, Philadelphia, and New York: W. B. Saunders and Co. Pp. 138. Price 13*s.* net.—The appearance of this English translation of Dr. Schaeffer's well-known "Atlas of Operative Gynæcology" is to be welcomed because there is nothing quite like it available for English readers. The book is edited by Professor Clarence Webster who has added various remarks and emendations of his own which increase the value of the work. The book gives a good idea of the author's experience and practice and on the whole is written in a judicious and clear manner. Some of the statements sound a little peculiar to English readers—for example, the statement on p. 80 that a weight extension may be used with a Barnes's bag. This is, of course, practically quite impossible but it can be done with a Champetier de Ribes's bag. Then, again, on p. 85 we are told that vaporisation of the uterus is contra-indicated in cases complicated with appendicitis; surely no surgeon would dream of performing any such operation on a woman suffering from an attack of appendicitis. The illustrations are very good and serve their purpose and on the whole the book is a satisfactory example of an atlas of operative work, always a difficult subject to treat in such a way. The translation is in parts rather crude and literal.

Midwifery for Midwives. By W. Denison Wiggins, M.R.C.S. Eng., L.R.C.P. Lond., D.P.H. With 44 illustrations. London: Baillière, Tindall, and Cox. 1904. Crown 8vo, pp. xv.—249. Price 3*s.* 6*d.* net.—This little book is designed to cover the requirements of the examining board authorised by the Midwives Act, 1902. The very good advice is given by the author that candidates would be well advised to obtain a certificate of efficiency in general nursing covering a period of three years before taking up this special branch of obstetric nursing. As he points out, in this way they come to the subject with a considerable amount of knowledge concerning technical terms and, more important still, with an appreciation of what is meant by surgical cleanliness, perhaps the most important of all requirements in a monthly nurse. This little book is clearly and succinctly written and the author has not committed the mistake of going into too much detail. We can recommend it as suited to the class for whom it is intended.

A Short Practice of Gynæcology. By Henry Jellett, B.A., M.D., B.Ch., B.A.O. Dub., ex-Assistant Master, Rotunda Hospital. Second edition, revised and enlarged. With 223 illustrations. London: J. and A. Churchill. 1903. Pp. 403. Price 10*s.* 6*d.* net.—A considerable amount of revision has been undertaken by the author in the preparation of the second edition of his well-known text-book on gynæcology. The work has been much enlarged and altered in size so that the page is a good deal larger and the figures are correspondingly clearer. Nearly 100 new illustrations have been added and they do much to render the work more valuable and attractive. The book will prove interesting not only to the student but also to the teacher as it gives him a clear exposition of the current teaching of the Dublin school of gynæcologists. As we said of the first edition, the book is written clearly and practically and evidently by one who is a good teacher and understands the value of method in his writings. It is a book which we have no hesitation in recommending strongly to the student and the second edition is no less likely to be received favourably than was the first.

A Complete Handbook of Midwifery for Midwives and Nurses. By J. K. Watson, M.D. Edin. London: The Scientific Press, Limited. 1904. Pp. 348. Price 6*s.* net.—As the author points out in his preface, the question as to whether in a book for midwives subjects should be dealt with which it is never intended the midwife should have anything to do with in the practice of her art, is a difficult one to decide. Dr. Watson thinks that the answer should be in the affirmative and accordingly his aim in writing this work has been "too much" rather than "too little." The wisdom of this procedure seems to us somewhat doubtful and we are inclined to think that the subject is considered in rather too great detail in this handbook. It will be of value to women with a good deal of general education who propose to become midwives, but we are afraid that the style in which it is written will make it too complex for the ordinary, only too often but poorly educated, woman who contemplates following this occupation. The whole subject of midwifery is carefully considered and there are two useful appendices, the first dealing with the nursing of gynæcological cases and the second giving in detail the more important of the rules for the guidance of midwives issued by the Central Midwives Board. The book is a useful one and likely to be of assistance to those women who are sufficiently well educated to avail themselves of its help.

JOURNALS AND MAGAZINES.

Edinburgh Medical Journal.—To the February number of this magazine Mr. Harold S. Barwell contributes an interesting article on Laryngeal Tuberculosis in which the prognosis and the treatment of this grave affection are discussed. At the present day the outlook for sufferers from this disease is perhaps less hopeless than was the case some years ago. A certain small proportion of cases appear to recover entirely if they are taken in time and treated hygienically. Only too often, however, palliative measures are all that are possible and of anæsthetic drugs suitable for laryngeal use Mr. Barwell prefers heroin hydrochloride. Surgical methods may be followed by good results in suitable cases. The author speaks of epiglottic cases as being of bad prognosis but it must be borne in mind that it is possible to remove this appendage with good effect. In an article on Anæsthetic Mixtures and Sequences in General Anæsthesia Mr. G. W. Bampfylde Daniell points out the great choice of such sequences which are at the disposal of the anæsthetist. Some interesting figures are given showing the gradual replacement of chloroform by "gas and ether" in the Edinburgh Dental Hospital since 1897. A review, in the form of an editorial note, of Dr. Sabouraud's recent book on "Pityriasis and Alopecia" gives a useful summary of the growth of knowledge with regard to these conditions of the skin.—The March number opens with an important article by Mr. A. Logan Turner upon the Operative Treatment of Chronic Suppuration in the Frontal Sinus. The comparative merits of preserving and of obliterating the sinus are discussed and allusion is made to a new method of procedure devised by Killian which is designed to admit of the radical treatment of the disease with a minimum of disfigurement. The author suggests that a collective investigation as to the results of treatment in disease of the sinus and of the antrum would be of considerable value. Dr. A. F. R. Conder reports two cases of Addison's Disease and compares with them that of an imbecile patient who exhibited very similar symptoms but post mortem the characteristic lesions of the suprarenal bodies were not found; he suggests that in this patient there may have been functional defect of the secretion. A paper by Mr. Archibald Stodart-Walker contains some disquieting reflections upon the decrease in the birth-rate and discusses its social causes. We cannot quite agree with the author in his attempt to trace the higher birth-rate among the lower classes to their possession of higher moral principles. We can hardly believe that it is the duty of every married couple to produce the greatest possible number of children without regard to their ability to give these children an education and a start in life such as will enable them to occupy their parents' position in the world. Prudence and self-respect are not necessarily vices, nor are their opposites virtues except in the eyes of the mere statistician.

Scottish Medical and Surgical Journal.—In the February number Dr. Stephenson continues his account of "Obstetric Views that Need Reviewing," the present (concluding) portion of his paper emphasising the importance of the property of retraction possessed by the uterine muscle in addition to its active muscular contraction. Retraction appears to be practically equivalent to elasticity. Dr. W. G. Aitchison Robertson deals with the important subject of the purity of our milk-supplies. He lays stress upon the necessity for insisting upon the maintenance of the strictest hygienic conditions in all dairies and cowsheds and advocates the sanctioning of the addition of small amounts of antiseptics to milk as a much smaller evil than allowing it to decompose. In a paper dealing with the Histology and Genealogy of Hæmophilia Dr. Alexander Goodall concludes that the disease is due to defective coagulation of the blood rather than to any anatomical defect in the vessels.—We are glad to read the sensible article contributed by Dr. Francis D. Boyd to the March number. He lays stress in the treatment of gastric ulcer on the simple and commonsense method of physiological rest. Dr. Boyd advises total starvation for a few days, the patient receiving only water per rectum. Surgical measures are only called for in cases of chronic ulceration or of recurrent severe hæmatemesis. Mr. G. F. Barbour Simpson records a case of Fatal Irreducible Prolapse of the Uterus and Dr. R. A. Fleming narrates his experiences in the treatment of advanced dilatation of the heart by massage and exercises, with which he is very favourably impressed.

Birmingham Medical Review.—In the January number of this review Mr. O. G. Higginson recalls the pioneer work done by Bodington and MacCormac in advocating the treatment of pulmonary tuberculosis by open air and plentiful feeding, and Mr. H. May discusses the birth-, marriage-, and death-rates as compared with the changes which have taken place in the age distribution of the population and comes to the conclusion that the correction thus introduced into the statistics only emphasises the depressing tendency of the figures. In the February issue Professor Jordan Lloyd discusses the technique of partial and complete removal of the tongue and Mr. F. Victor Milward advocates the use of the sigmoidoscope in cases of rectal disease, pointing out that the use of Strauss's instrument is not very painful to the patient while it enables a full view to be obtained of a considerable length of the bowel.

Annals of Ophthalmology. Edited by JAMES MOORE BALL, M.D. St. Louis, Missouri, U.S.A.: Jones H. Parker. Vol. XIV. No. 1. January, 1905. Annual subscription for four quarterly parts, 18*s*.—This journal contains 15 original articles and a large number of abstracts from the ophthalmic literature of America and England, France, Germany, Spain, and Italy, which are done well on the principle of the division of labour, each subject being placed by the editor in the hands of one familiar with the language. Amongst the more interesting of the original articles are (1) that by Henry D. Bruns, M.D., of New Orleans, on the Removal of the Lens in High Myopia. Dr. Bruns holds that extraction of the lens is strongly to be advised in extreme myopes between the ages of 10 and 25 years. The prophylactic value of the operation is very great and the operation should consist in repeated discission. One eye only should be operated on at a time and a considerable interval should elapse before the second eye is attacked. The operation is contra-indicated for extreme myopes of, or beyond, middle age, especially in those in whose eyes extensive pathological changes have taken place. 2. An article by Dr. Bourgeois of Rheims on the Treatment of the Accidents of Infection after the Operation for Cataract. 3. A note by W. N. Souter, M.D., correcting a common misconception of Astigmic Refraction. 4. Dr. Liebreich discusses the Influence of the School upon the Eye and Spinal Column, in which he gives the result of his ripe experience on this subject. The number is adorned by a frontispiece consisting of the portrait by Faber after Ryche in mezzotint of the well-known charlatan-oculist, John Taylor, who lived in the eighteenth century and was oculist to George II., and there is also a plate copied from Hogarth's "Consultation of Physicians," in which that great painter has given free play to his humour in caricaturing the heads of the profession in his day.

National Service Journal.—We have received a copy of the February issue of this journal, the official organ of the league which bears this name. The emblematic cover represents Peace armed with shield and spear whom a figure representing War is apparently afraid to attack. A cartoon among the contents of the journal entitled "The Path of Duty is the Path of Safety" shows a youth being led by Duty through the forest of Ignorance. This picture, which is intended of course to convey an important moral lesson, might well be a little less suggestive of a scene from a pantomime. The articles on the National Significance of Universal Training, Naval Lessons of the War, and other subjects of an imperial interest will no doubt be read with the attention which they deserve. The price of the journal is 3*d*. and it can be obtained at Dacre House, Victoria-street, Westminster, S.W.

Reports and Analytical Records

FROM

THE LANCET LABORATORY.

STERILISOL.

(DR. A. FOELSING, FRANKFURT A M. AGENCY, DUFFIELD AND FUNK, 3, LOVE-LANE, EASTCHEAP, E.C.)

STERILISOL is an aqueous solution of trioxymethylene which is a polymer of formaldehyde. Hitherto it has not been found practicable to prepare an aqueous solution of trioxymethylene free from formaldehyde or, what is the same thing, oxymethylene. In fact, when trioxymethylene is dissolved in water under ordinary conditions some dissociation takes place, formaldehyde forming. If, however, the trioxymethylene is dissolved in water at from 40° to 45° C. in vacuo there is no separation of formaldehyde. Sterilisol represents an aqueous solution of trioxymethylene free from formaldehyde or oxymethylene. On evaporation in vacuo a residue of trioxymethylene is obtained. On the other hand, a solution of formaldehyde evaporated in vacuo yields no residue. The preparation is, like its prototype, an exceedingly powerful antiseptic, germicide, and deodorant; and it is doubtless, as it is claimed to be, an effective preservative, but it seems to us that its use for preserving food is open to the same objection as is formaldehyde. The solution is neutral in reaction and on boiling in the open air gives off formaldehyde. Sterilisol rapidly reduces alkaline solutions of silver salts.

GLUTEN BREAD.

(LACOSTE FRÈRES, VILLEMUR, FRANCE. AGENTS. C. THEELKF, 106B, CASTWICK-ROAD, WEST NORWOOD.)

The old form of gluten bread—that is, a puffed-out loaf—is very well represented in this preparation. According to our analysis the bread contains 75 per cent. of gluten, the balance, 25 per cent., being accounted for by starch and a trifling amount of mineral matter. This bread supplies, of course, a loaf which is suitable for the use of those who are forbidden a carbohydrate diet.

SPANISH BRANDY.

(JIMENEZ AND LAMOTHE, MALAGA AND MANZANARES. AGENCY: FREDK. BOEHM, 16, JEWRY-STREET, LONDON, E.C.)

We have on more than one occasion pointed out that excellent brandy is distilled in Spain and some security is obtained as to its genuineness by the fact that the excise regulations in that country in regard to foreign spirit (grain and potato spirit) practically prohibit the adulteration of brandy with spirit that is not derived from the grape. It is fortunate when excise regulations protect the consumer and when, as a matter of fact, it is unprofitable to the producer in the case of brandy to use anything else but grape spirit. We wish that such were the case in this country. This sample is an excellent brandy and we have no doubt that it is not only a genuine grape spirit but one that has been produced in the pot still. The following analysis in regard to secondary products sustains this view. The results, given in grammes per hectolitre of absolute alcohol present, were as follows: acidity reckoned as acetic acid, 50·00; aldehyde, 26·00; furfural, 1·90; ethers reckoned as ethyl acetate, 90·00; and higher alcohols, 104·00: total secondary products, 271·90. *These figures* agree very closely with those obtained in the analysis of genuine Cognac brandy. The exception, however, occurs in regard to the amount of aldehyde which is in excess of that generally obtained with Cognac brandies, aldehydes, in fact, being a feature of the distillate of Spanish white wines. Further results of analysis were obtained as follows: alcohol, by weight 40·90 per cent., by volume 48·32 per cent., equal to proof spirit 84·68 per cent.; extractives, 1·54 per cent.; and mineral matter, 0·03 per cent. The flavour is acceptable, though somewhat "fuller" than delicate vintage brandies, and is distinctly sweet. The sweetness, however, is not due to sugar. This brandy, on the whole, as regards finesse, bouquet, &c., bears a distinct resemblance to the Cognac product.

(1) SOLUBLE INFANT'S FOOD (THEINHARDT); AND (2) HYGIAMA (THEINHARDT).

(AGENTS: C. HOHMANN, 33, SEETHING-LANE, LONDON, E.C.)

Both these preparations have received our attention on a previous occasion but they have since been improved, it is stated, by increasing the proportion of proteid and fat and of carbohydrates soluble in water. On comparing our recent examination with that made 12 years ago we find that this statement is true. In the case of the infant's food in particular the fat has been advanced from 5 to nearly 8 per cent. while of the 70 per cent. of carbohydrates nearly 54 per cent. are soluble in water; and in "hygiama," while the fat remains the same, all but 10 per cent. of the carbohydrates, which amount altogether to 60 per cent., are soluble in water. Both preparations contain a high proportion of proteid, the infant's food just over 16 per cent. and "hygiama" nearly 22 per cent. The preparations belong to the class of malted farinaceous foods in which the constituents are rendered soluble to a large extent and digestible by diastasic action.

SYLVIA SOAP.

(THE SYLVIA SOAP CO., 62, COLEMAN-STREET, LONDON, E.C.)

Sylvia soap is described as a pure neutral soap "with which are incorporated certain animal principles which are absorbed by the skin and exert a solvent action on the underlying adipose tissue." We agree that the soap is a pure neutral soap but we must confess to great misgivings as to its power of reducing corpulency, and we can find no record of practical evidence on this point. As to what the certain animal principles are we may make a shrewd guess after finding that the soap gives a very marked reaction characteristic of biliary acids. Thus when a solution of glucose in strong sulphuric acid is poured into a pool of a solution of the soap a brilliant play of crimson colours is produced. The soap contains a mineral substance of the nature of French chalk. These results coincide with those which we obtained with a soap known as "amiral" soap, noticed in THE LANCET of July 30th, 1898, p. 266.

New Inventions.

THE "LOCKET" POISON BOTTLE.

WE have received from the Locket Patents Company a sample of a new poison bottle which presents some distinctive features. It somewhat resembles the round ended inverted bottles commonly used in museums and shops for the display of specimens. These bottles usually have a glass stopper with a large flattened head on which they stand but the poison bottle is closed with a cork inserted in a neck of the usual description. The shoulder of the bottle close to the neck has an external screw-thread in the glass and on it there screws a flat-ended cap which supports the bottle in the vertical position with the rounded extremity uppermost. It is, therefore, impossible even for a blind person to mistake this poison bottle for one of the ordinary kind. The bottle is of transparent blue glass; including the cap its dimensions are five and three-quarter inches high and one and a half inches in diameter. The address of the Locket Patents Company is 6, Mornington-place, Hampstead-road, London, N.W.

Looking Back.

FROM

THE LANCET, *SATURDAY*, April 21, 1827.

Insanity was very common during the commonwealth; cant and impiety and murder, were the orders of the day Cromwell, at least, was mad: his chaplain, Godwin, told him, that the elect would never be damned; then "I am sure," says he, "that I am safe; for I was once in a state of grace." On his death bed, "I tell you," cried he to his physicians, who had warned him of his end, "that I shall not die of this distemper; I am well assured of my recovery; favourable answers have been returned from heaven, not only to *my own* supplications, but likewise to those of the godly, who have a more close correspondence with God *than* I!" Other parts of his life may be quoted in proof of the delusion; nor was he solitary in his madness. When Colonel White went with an armed band to dissolve the parliament of the times, he found one Moyer in the chair, who being asked what they did there, replied that they were seeking the Lord; "Then you may go elsewhere," cried White, who was clear of the delusion, "for, to my certain knowledge, the Lord has not been here these many years." It is clear, therefore, that a species of theo-mania was very common at that period.* Plagues and influenzas were also common. Is it too much to suppose that the atmospherical causes which produced the one, had some share in producing the other? We well know, that some conditions of the body change with the weather; why not the brain? On the day Cromwell died (Sept. 3, 1658,) there was a violent storm, which the influence of the sun and moon had some share in raising; and it is certain that *madmen* are worse, and that other effects are produced on animals at the quadratures of the moon. The idea of this influence will, we dare say, be laughed at; but beyond all doubt, considerable changes are produced in animal bodies, about the period of the autumnal and vernal equinoxes. The weather has much concern with diseases, and the sun and moon most assuredly have much effect on the weather; they must, therefore, be allowed to have a particular influence on animals, indirectly, at the least.[1]

---

* Notwithstanding the delusion so common in that day, these people were shrewd and politic, and conducted the affairs of the nation with an energy unknown before. It is evident, therefore, that the manifestations of one or more faculties of the mind may be deranged or destroyed, without affecting the others; and hence it is perfectly unreasonable that a man should be deprived of his liberty and his rights, because he may happen to hold opinions upon a subject or two discrepant with those of his neighbours, unless his false perception of things be likely to lead to violence or crime.

[1] Excerpt from lengthy reviews of three books on insanity by the following authors respectively, viz., J. G. Spurzheim, M.D., Paul Slade Knight, M.D., and Alexander Morison, M.D.

FOREIGN UNIVERSITY INTELLIGENCE.—*Copenhagen:* The gold medal offered for an essay on Colour Blindness has been awarded to Dr. Henning Chr. Trappaud Rönne.—*Giessen:* Dr. Johann Georg Mönckeberg has been recognised as *privat-docent* of General Pathology and Pathological Anatomy. Dr. Best, *privat-docent* of Ophthalmology, and Dr. Boetticher, *privat-docent* of Surgery, have been promoted to Extraordinary Professorships.—*Gottingen:* Arrangements have been made with Dr. Ehrlich, Director of the Institute of Experimental Therapeutics in Frankfort, to deliver a course of lectures in this university, in which he is an honorary professor.—*Leipsic:* Dr. Garten, *privat-docent* of Physiology, and Dr. K. Hirsch, *privat docent* of Medicine, have been promoted to Extraordinary Professorships.—*Tübingen:* Dr. Dietrich, Assistant in the Pathological Institute under Professor Baumgarten, has been promoted to an Extraordinary Professorship.

THE LANCET.

LONDON: SATURDAY, APRIL 22, 1905.

Industrial Alcohol.

IT has long been to the prejudice of a certain large section of the trade of this country that alcohol used exclusively for the purposes of manufacture has had to bear revenue expenses which make it far more costly to English manufacturers than it is to manufacturers abroad. Indeed, the decadence of certain home industries is attributed in some quarters to the facilities generally afforded to foreign manufacturers for obtaining cheap alcohol. While undoubtedly there exist obstacles to the progress of certain industries in this country on account of the high price of alcohol compared with that which obtains abroad, it is a mistake to suppose that Germany's scientific industries have advanced entirely for that reason. The great coal tar dye industry, for example, was founded in this country but its rapid development in Germany practically ruined the manufacture here, not because alcohol was dear but because our manufacturers were so slow to realise the value of the application of scientific principles to the processes of manufacture. There is far too much of "the rule of thumb" principle still existing amongst our manufacturers who have earned for themselves the reproachful title of "thumbers." However, it is easy enough to mention a goodly list of industries in the country which are undoubtedly heavily handicapped against foreign traders by the relatively high price of alcohol and it is, therefore, reassuring to learn that the Departmental Committee on Industrial Alcohol, in its report just issued, believes that the recommendations which it has made will (if adopted) place the manufacturers of this country, in respect of the use of alcohol in the industries, on a footing of equality (in some respects of advantage) with their competitors abroad.

Practically, the committee suggests that the only adequate course to take in regard to reducing the price of alcohol is to neutralise for industrial spirit the enhanced cost of production due to excise control. This enhanced cost is already neutralised in the case of exports by granting an allowance on such spirit at such rate as may from time to time be taken as the equivalent of the increase in cost of production due to revenue restrictions. At the present time the rate is taken at 3*d.* per proof gallon for plain spirit and the allowance would accordingly be at this rate and should, the committee thinks, be paid equally on all industrial spirit, whether it be of British or of foreign origin. It is further recommended that ordinary methylated spirit should contain only 5 per cent. of wood naphtha instead of 10 per cent. This is calculated to cheapen methylated spirit while it will diminish any prejudicial effect that the chemical properties of wood naphtha may have in certain manufactures, and at the same time it will continue to ear-mark the spirit sufficiently to allow detection by analysis should the methylated spirit be used for any improper purpose. If these recommendations be adopted it is calculated that the average price of industrial spirit in the United Kingdom will be even lower than the average price in Germany. Further, it is calculated that these concessions will cause to the revenue an annual loss of over £40,000. The committee recognises the important part that alcohol plays in the preparation of pharmaceutical products and fine chemicals. It points out—and we believe it is justified in the statement—that cheap alcohol is perfectly compatible with the requisite quality and character of the compounds produced. A difficulty arises, however, in this case, because there are large numbers of pharmaceutical preparations in which the alcohol remains as free spirit and which must continue to be made from duty-paid spirit. Besides, pharmaceutical preparations are so numerous and so various in character that there are difficulties in making a single process of "denaturing" applicable to them all. These difficulties have been overcome in Germany and there is no reason why they should not be overcome here. The committee recommends that in the manufacture of fine chemicals and pharmaceutical products spirit specially "denatured" should be allowed only where the manufacture is kept entirely separate from the manufacture of tinctures and other preparations in which spirit remains as spirit in the finished products. Finally, it is suggested that the regulations governing the sale by retail of mineralised methylated spirit should be made less stringent and more elastic than hitherto. The committee does not regard the question of the use of spirit for motor-cars as ripe for consideration from the point of view of its inquiry, whilst the use of cheap alcohol for illuminating purposes seems to have escaped its attention altogether.

The Chancellor of the Exchequer has expressed his intention of adopting the recommendations and it is interesting to note that one effect of their adoption may be that the manufacture of industrial alcohol will be encouraged in this country and that after all the growing of potatoes may pay for the sake of the spirit which can be made from them. It is probable also that these concessions will favourably affect the prices of many drugs and that the old preference for English-made goods will not be checked by considerations of extra expense.

A Convalescent Homes Association.

THERE can be no difference of opinion as to the value of convalescent homes. When a patient is discharged from a hospital he is often not yet fit to resume his occupation. He may have recovered from the illness from which he has suffered or the operation which he has undergone but he has not the strength to do his ordinary work. For such a man a short stay at a convalescent home, in the pure air of the country or of the seaside, may suffice to render him more capable of working than he was even before he sought treatment at the hospital. In many cases complete recovery may ultimately ensue even if a sojourn at a convalescent home is impossible, but often a cure will be indefinitely prolonged in the unhealthy conditions of the patient's own dwelling. In most cases recovery is not only much more rapid but also much more complete when suitable acid, 50·00; aldehyde, 26·00; furfural, 1·90; ethers reckoned as ethyl acetate, 90·00; and higher alcohols, 104·00: total secondary products, 271·90. These figures agree very closely with those obtained in the analysis of genuine Cognac brandy. The exception, however, occurs in regard to the amount of aldehyde which is in excess of that generally obtained with Cognac brandies; aldehydes, in fact, being a feature of the distillate of Spanish white wines. Further results of analysis were obtained as follows: alcohol, by weight 40·90 per cent., by volume 48·32 per cent., equal to proof spirit 84·68 per cent.; extractives, 1·54 per cent.; and mineral matter, 0·03 per cent. The flavour is acceptable, though somewhat "fuller" than delicate vintage brandies, and is distinctly sweet. The sweetness, however, is not due to sugar. This brandy, on the whole, as regards finesse, bouquet, &c., bears a distinct resemblance to the Cognac product.

(1) SOLUBLE INFANT'S FOOD (THEINHARDT); AND (2) HYGIAMA (THEINHARDT)

(AGENTS. C. HOHMANN, 33, SEETHING-LANE, LONDON, E.C.)

Both these preparations have received our attention on a previous occasion but they have since been improved, it is stated, by increasing the proportion of proteid and fat and of carbohydrates soluble in water. On comparing our recent examination with that made 12 years ago we find that this statement is true. In the case of the infant's food in particular the fat has been advanced from 5 to nearly 8 per cent. while of the 70 per cent. of carbohydrates nearly 54 per cent. are soluble in water; and in "hygiama," while the fat remains the same, all but 10 per cent. of the carbohydrates, which amount altogether to 60 per cent., are soluble in water. Both preparations contain a high proportion of proteid, the infant's food just over 16 per cent. and "hygiama" nearly 22 per cent. The preparations belong to the class of malted farinaceous foods in which the constituents are rendered soluble to a large extent and digestible by diastasic action.

SYLVIA SOAP.

(THE SYLVIA SOAP CO., 62, COLFMAN STREET, LONDON, E.C.)

Sylvia soap is described as a pure neutral soap "with which are incorporated certain animal principles which are absorbed by the skin and exert a solvent action on the underlying adipose tissue." We agree that the soap is a pure neutral soap but we must confess to great misgivings as to its power of reducing corpulency, and we can find no record of practical evidence on this point. As to what the certain animal principles are we may make a shrewd guess after finding that the soap gives a very marked reaction characteristic of biliary acids. Thus when a solution of glucose in strong sulphuric acid is poured into a pool of a solution of the soap a brilliant play of crimson colours is produced. The soap contains a mineral substance of the nature of French chalk. These results coincide with those which we obtained with a soap known as "amiral" soap, noticed in THE LANCET of July 30th, 1898, p. 266.

New Inventions.

THE "LOCKET" POISON BOTTLE.

WE have received from the Locket Patents Company a sample of a new poison bottle which presents some distinctive features. It somewhat resembles the round ended inverted bottles commonly used in museums and shops for the display of specimens. These bottles usually have a glass stopper with a large flattened head on which they stand, but the poison bottle is closed with a cork inserted in a neck of the usual description. The shoulder of the bottle close to the neck has an external screw-thread in the glass and on it there screws a flat-ended cap which supports the bottle in the vertical position with the rounded extremity uppermost. It is, therefore, impossible even for a blind person to mistake this poison bottle for one of the ordinary kind. The bottle is of transparent blue glass; including the cap its dimensions are five and three-quarter inches high and one and a half inches in diameter. The address of the Locket Patents Company is 6, Mornington place, Humpstead-road, London, N.W.

Looking Back.

FROM

THE LANCET, *SATURDAY*, April 21, 1827.

Insanity was very common during the commonwealth; cant and impiety and murder, were the orders of the day Cromwell, at least, was mad: his chaplain, Godwin, told him, that the elect would never be damned; then "I am sure," says he, "that I am safe; for I was once in a state of grace." On his death bed, "I tell you," cried he to his physicians, who had warned him of his end, "that I shall not die of this distemper; I am well assured of my recovery; favourable answers have been returned from heaven, not only to *my own* supplications, but likewise to those of the godly, who have a more close correspondence with God than I!" Other parts of his life may be quoted in proof of the delusion; nor was he solitary in his madness. When Colonel White went with an armed band to dissolve the parliament of the times, he found one Moyer in the chair, who being asked what they did there, replied that they were seeking the Lord; "Then you may go elsewhere," cried White, who was clear of the delusion, "for, to my certain knowledge, the Lord has not been here these many years." It is clear, therefore, that a species of theo-mania was very common at that period.[*] Plagues and influenzas were also common. Is it too much to suppose that the atmospherical causes which produced the one, had some share in producing the other? We well know, that some conditions of the body change with the weather; why not the brain? On the day Cromwell died (Sept. 3, 1658,) there was a violent storm, which the influence of the sun and moon had some share in raising; and it is certain that madmen are worse, and that other effects are produced on animals at the quadratures of the moon. The idea of this influence will, we dare say, be laughed at; but beyond all doubt, considerable changes are produced in animal bodies, about the period of the autumnal and vernal equinoxes. The weather has much concern with diseases, and the sun and moon most assuredly have much effect on the weather; they must, therefore, be allowed to have a particular influence on animals, indirectly, at the least.[1]

---

[*] Notwithstanding the de[illegible] that day these people were shrewd and politic, an[illegible] an energy unknown before. [illegible] tions of one or more faculties of the mind may [illegible] without affecting the others; and hence it is perfectly unreasonable that a man should be deprived of his liberty and his rights, because he may happen to hold opinions upon a subject or two discrepant with those of his neighbours, unless his false perception of things be likely to lead to violence or crime.

[1] Excerpt from lengthy reviews of three books on insanity by the following authors respectively, viz., J. G. Spurzheim, M.D., Paul Slade Knight, M.D., and Alexander Morison, M.D.

FOREIGN UNIVERSITY INTELLIGENCE.—*Copenhagen:* The gold medal offered for an essay on Colour Blindness has been awarded to Dr. Henning Chr. Trappaud Rönne.—*Giessen:* Dr. Johann Georg Mönckeberg has been recognised as *privat-docent* of General Pathology and Pathological Anatomy. Dr. Best, *privat-docent* of Ophthalmology, and Dr. Boetticher, *privat-docent* of Surgery, have been promoted to Extraordinary Professorships.—*Gottingen:* Arrangements have been made with Dr. Ehrlich, Director of the Institute of Experimental Therapeutics in Frankfort, to deliver a course of lectures in this university, in which he is an honorary professor.—*Leipsic:* Dr. Garten, *privat-docent* of Physiology, and Dr. K. Hirsch, *privat-docent* of Medicine, have been promoted to Extraordinary Professorships.—*Tübingen:* Dr. Dietrich, Assistant in the Pathological Institute under Professor Baumgarten, has been promoted to an Extraordinary Professorship.

only a tunnel-like entrance and with a consequent absence of circulation of air. The corporation has power to deal with such buildings under a local Act, the Liverpool Sanitary Amendment Act, 1864, and in doing so it has to face the fact that in its worst districts near the docks the population is not only very poor but is engaged in casual labour, which necessitates application for work four times in 24 hours, so that rehousing in distant suburbs is out of the question.

The initiation of the present policy appears to have been due to the discovery that the number of tenants displaced by the demolition of their houses who afterwards occupied the new ones provided by private or by municipal enterprise was infinitesimal owing to the higher rents of the improved dwellings, the natural inference being that the displaced population found its way into old houses which were insanitary and were awaiting their turn for demolition. Consequently demolition and rebuilding have been so arranged that for some years past no tenant has been dispossessed by the operations of the corporation without having been given the opportunity of occupying one of the new tenements provided. The dwellings usually erected at Liverpool by the corporation are three storeys in height, the living rooms containing 150 superficial feet and the bedrooms from 125 to 80 feet, with an average height of nine feet, and the materials used are serviceable and conducive to sanitary efficiency. The rents range from 5*s.* 3*d.* to 4*s.* 6*d.* per week for four-roomed tenements, with corresponding grades for those containing three and two rooms, the cheapest two-roomed dwellings costing 2*s.* 9*d.* per week to the tenant. Financially, a rate of about 2*d.* in the £ is at present sufficient to meet the annual cost to the municipality entailed by the building operations which have taken place, and as a portion of this is set aside for the repayment of the loans raised the time is looked forward to in each instance when the new houses will be a valuable asset producing a regular and not inconsiderable rental. Looked at from a sanitary and moral point of view, these new houses, containing, be it remembered, the same inhabitants as the old ones, appear to be productive of considerable improvement in the crowded quarters in which they are situated. The death-rate prevalent in the unhealthy areas which have been dealt with reached on an average, according to Mr. TURTON'S figures, 60 per 1000 per annum. The death-rate in the new dwellings is at the present time about 25 per 1000 per annum, and it must not be forgotten that where this lower rate is found the families have lived hitherto in unhealthy surroundings, so that they must be considered still to feel the influence of the unfavourable conditions from which they have been saved. These figures by themselves are an eloquent testimony to the importance of the housing question and to the practical and ascertainable nature of the results which can be arrived at by judicious measures.

No less important are the facts relating to the moral and the social aspect of the case. Mr. TURTON records from his own observation the outward signs of personal improvement on the part of the families removed to the new buildings, the increasing cleanliness of the houses, the polishing of door handles, the gradual provision of window curtains and even of plants, and the additions made to the scanty store of furniture. Statistically he supports his case with figures furnished by the chief constable, from which the following may be cited. In 1894 in a typical district before demolition of the insanitary buildings began there was a total population of 1393 persons and the number of those charged with drunkenness, with assaults, and with other offences who gave addresses in the streets included was 202, while 64 arrests took place within the area. In 1904, ten years later, new houses had taken the place of the old ones, accommodating 1246 persons, and these had been occupied for a year. During the same length of time the corresponding figures were 84 and 12 respectively. If improved conditions such as these can be brought about and maintained by placing the poorest of our citizens in healthier homes and thereby increasing their self-respect and their desire to lead decent lives, it would seem that a substantial *proportion of the* money expended must necessarily be repaid by the economy effected in other directions. Liverpool is to be congratulated upon the success which has attended a business-like method of dealing with a difficult question and its citizens should be encouraged to persevere in the completion of the work which they have begun. They commenced it in 1864, when the Act of Parliament referred to was passed and when it was estimated that there were 22,000 structurally insanitary houses. In 1902 it was found that nearly 10,000 houses remained to be dealt with, and though this figure shows that much is yet to be done Londoners will hardly be able to help envying a city in which the task of housing the working classes may be said to be of reasonable dimensions. It must be noticed, however, that even the system adopted at Liverpool does not provide for all those displaced. According to Mr. TURTON there is always a residuum who cannot face the change. These have lived, and will continue to live, from hand to mouth, paying no rent where it is possible to avoid it, and shunning habitations such as those under municipal control, where the payment of rent and a certain amount of decency of conduct are indispensable conditions of tenancy. Although some of these will remain to spread disease and vice until the last slum has been levelled and rebuilt, their numbers will grow less as the habitations which shelter them grow fewer and as the conditions which contribute to the increase of their numbers are ameliorated.

Annotations.

"Ne quid nimis."

GALL-STONES AND CANCER.

FOR many years it has been believed that the association of gall-stones with malignant disease of the gall-bladder or biliary passages is very common, and when careful statistics bearing on the subject have been prepared no doubt can remain that a large proportion of persons who suffer from gall-stones die from carcinoma of the biliary tract and that in nearly all cases of malignant disease of this region gall-stones are present or a history of their previous existence can be obtained. Whatever theory we may hold as to the etiology of malignant disease this connexion is clear. Dr. G. R. Slade of the London Hospital has been carefully investigating the cases in that institution in which gall-stones have been found at the post-mortem examination or in which malignant disease of the gall-bladder has been present. The results are very striking. In all 33 cases of gall-stones were discovered amongst 2180 consecutive complete necropsies and in just one-half of these (17 out of 33) no symptoms indicating gall-stones had been present and in all but one of these 17 cases there was no naked-eye evidence of malignant disease, while in the remaining case microscopical examination showed carcinoma. Of the 16 cases where symptoms had been present nine gave definite evidence of the presence of malignant disease, but in the other seven cases, though macroscopically "chronic inflammatory thickening" was present, no histological examination was made. Thus we see from these figures that in 30 per cent. of all cases of gall-stones malignant disease was present as it was in 56 per cent. of all cases where gall-stones had caused symptoms during life. It is very probable that these figures understate the frequency of the association of gall-stones and cancer, for several of the cases where the cystic wall was thickened were not investigated microscopically and may very possibly have been malignant. If it be admitted, then, as admitted it must be, that these two conditions are causally connected, it remains to be decided which of the two is the cause and which the effect; or it is possible that both may be alike effects of a common cause. The supposition need not detain us, though it has been held that as some are inclined to ascribe gall-stones to an excessive diet of meat, so others have been equally certain that malignant disease has a similar origin. Inasmuch as in almost all the cases of carcinoma gall-stones were present, while in as many cases gall stones were present in the gall-bladder but there was no evidence of malignant disease, we are bound to acknowledge that it is almost certain that the gall-stones give rise to the cancer and not the cancer to the gall-stones. In elucidation of the question, How can gall-stones cause malignant disease? we have the fact shown by statistics that carcinoma is especially likely to accompany gall-stones if they are rough and irregular on the surface. Therefore, it is probable that, as in other parts of the body, local irritation tends to excite, or to assist in exciting, malignant disease. What additional cause is necessary we do not know. Recent bacteriological research has shown that many morbid hepatic conditions are microbic in origin which were formerly looked upon as of other etiology. This fact of itself might suggest that possibly in malignant disease of the gall-bladder also we have a micro-organism as a causative factor in addition to the local inflammation. Be this how it may, we can feel assured that we are not in error in ascribing carcinoma of the gall-bladder to the chronic irritation and injury caused by gall-stones with some additional etiological element at present unknown to us. The practical bearing of the close association of gall-stones and malignant disease of the gall-bladder is obvious. If it be true that over 50 per cent. of all cases of gall-stone end in malignant disease, and this must certainly be admitted, it should follow as a necessary corollary that total removal of the gall-bladder in cases of cholelithiasis would be preferable to mere cholecystotomy and evacuation of the stones, provided always that the increase of the danger of the operation was not enough to counter balance the improved prognosis should the operation succeed. In the hands of a skilled operator the increase in the risk is but small and when cholecystectomy is performed there is the additional advantage that the chance of a biliary fistula is obviated. The physiological value of the gall-bladder is slight, so that its loss is not felt so far as we are aware. Dr. Slade's paper (which is published at p. 1059 of our present issue) is a good example of the utility of careful statistical inquiries and we hope that he will continue his investigations into this important matter.

INFANTILE MORTALITY.

AT a recent meeting of the Prestwich board of guardians the third report of Miss Pollitt, the inspector under the Infant Life Protection Act, was read. She said that there were 29 infants on her register; 20 were illegitimate, 14 of them being entirely supported by their mothers who were domestic servants. She stated that instead of decreasing the rate of infantile mortality was increasing, notwithstanding all the improvements in the conditions of life. She could only put it down to the ignorance and the neglect of the mothers. We may well wonder whether, with all the costly and elaborate arrangements for teaching accomplishments in our elementary schools, it will ever occur to doctrinaire educationists that there are practical matters affecting the life and the well-being of poor people which will not be solved satisfactorily until more attention is given to subjects bearing on health and everyday duties.

OIL IN TOBACCO.

WE have received from the Scottish Anti-tobacco Society a communication in which it is suggested by Mr. Rutherford Hill that the irritating effects of tobacco smoke may be largely due to the combustion of oil. Tobacco, of course, contains a natural oil but for the purpose of manufacture the practice of adding oil is on the increase, as was shown in the last report of the principal chemist of the Government laboratory. The oil used is stated to be best Florence oil, which on imperfect combustion would yield the intensely acrid and irritating vapour, acrolein. While we quite agree that the formation of acrolein in this way would be a contributory factor to the irritating property of tobacco smoke, yet it must be borne in mind that the products of the destructive distillation of the tobacco leaf, even free from added oil, contain a great number of substances of a similarly acrid character. Such, for instance, are pyridine, furfural, butyric and valeric acid, ammonia compounds, and so forth. The addition of glycerine which is also practised would again give rise to the formation of acrolein, while glucose would give irritating products on partial combustion. The proportion of added oil, glycerine, or glucose is, however, in most cases small and probably insignificant having regard to the proportion of tobacco smoked. We object, however, to the principle in general of adding any foreign substance whatever to tobacco and the less tampering there is with the leaf the better and the less injurious is it likely to be. But it seems to us that we do not require to resort to an enumeration of the various constituents, good or bad, of tobacco to prove that smoking by juveniles is a pernicious practice. Any movement to suppress the habit amongst children has our complete approval.

THE DANGERS OF THE STREETS.

A CORRESPONDENT in addressing us upon the subject of the dangers to pedestrians in the London streets includes in his indictment the hat-pins of the women—"unclean imitations," he terms them, "of the ladies' dagger of the Middle Ages,"—and the bad language of the men. There is much force in his contention that both hat-pins in women's heads and oaths in men's mouths do form public dangers. Among a certain class hat-pins are constantly used as weapons of offence and when they are not employed in this manner by the design of the wearer they often threaten the eyes of others in a really dangerous way. It ought to be possible for an ingenious milliner to devise some less dangerous method of fixing on the hat. Nor is the modern headgear of women without its pathological significance. On a windy day the leverage on the roots of the hair when the large and flapping headgear is endeavouring to sail away is one of the causes of the headache of which most women complain after a buffeting by the elements. *Il faut souffrir pour être belle* is an old saying, but many women do not know that they have only their hats to thank for their headaches, while the aphorism does not suggest that the eyesight of other people should suffer for beauty's sake. The evil caused by thoughtless men who do not sufficiently restrain themselves in their use of unseemly language cannot be exactly estimated. It can only be guessed at, but the fact remains that it is quite impossible for women to pass along many of our streets without their ears being assailed by expressions which must insensibly affect them. In puerperal and even in other forms of insanity nothing astonishes the friends more than the indecent expressions and the oaths used by the patient. They cannot understand where and how these phrases have been acquired. There are, unfortunately, too many opportunities for the incorporation into the mental life of objectionable elements which, at first latent, declare themselves in all their objective repulsiveness when the patient becomes a reflex machine, as it were a phonograph reproducing the impressions of these street vulgarisms.

THE DISCOVERY OF THE DISCOVERED.

M. O. van Schoor in an essay in the *Journal de Pharmacie* for March on the evolution of medicine accentuates the truth of the adage, *Nil novi sub sole*. Some of his illustrations are worth giving. Hippocrates was aware of the patches in the intestines the discovery of which is ascribed to Peyer (1680), and Caspar Aselli (1600) is wrongly said to have discovered the chyliferous vessels to which Herophilus and Erasistratus drew attention (250 B.C.). The pancreatic duct, the discovery of which is attributed to Hoffman and Wirsung (1630), is mentioned by Eudemus, a contemporary of Galen. Again, Alcmæon, who lived in the fourth century before Christ, refers to the auditory duct which afterwards bore the name of Eustachian tube. The same thing has occurred in therapeutics. Many remedies that were employed in remote antiquity fell into disuse and were again introduced into practice at a later date. Thus, arsenic was used as a febrifuge by Lentilius and Hippocrates recommended it for cancerous affections. The most recent researches have resulted in the employment of arsenic for the same purpose in the form of organic compounds—e g., the cacodylates and arrhenal. Pythagoras recognised the diuretic value of squill but its use lapsed for a long period. Opium has been found in the dwellings of the inhabitants of the lake villages of Switzerland as well as in ancient Egyptian tombs, but afterwards it appears to have been forgotten during several centuries. Hippocrates employed this drug freely as a sedative and afterwards it had a vogue in the Middle Ages. Even Paracelsus did not scruple to use this vegetable drug in the case of one Kornel von Lichtenfels who had vainly tried other practitioners without being cured. Paracelsus speedily effected a cure but it is of interest to note that the patient refused to pay the fee which had been agreed upon before the treatment was begun. The case was tried before the court at Baslé, with the result that the fee was reduced to a few florins. This so angered Paracelsus that he reproached the judge and so brought about his banishment and the loss of the chair which he occupied in the university. A remedy known to Galen was the male fern which after the lapse of centuries was brought to the notice of Louis XIV. by a quack. In surgery it is no less true that some of the methods employed by modern advanced surgeons were known to the ancients. Thus Hippocrates mentioned intubation of the larynx and Cœlius Aurelianus gave instances of the successful operation of tracheotomy. Praxagoras ventured to perform a laparotomy, and employed intestinal sutures. Operations for hernia were performed 250 B.C. and Serapion removed diseased kidneys. P[illegible] in 1650, af[illegible] That the p[illegible] by the fact that contemporaries of Hippocrates were in the habit of dipping their instruments in boiling water. In the thirteenth century it was customary before operating to administer to patients by means of sponges placed in the nose the juices of sedative plants—e.g., stramonium, belladonna, and mandragora, consciousness being regained by the application of vinegar compresses. Among other methods of treatment now in vogue hydrotherapy, gymnastics, and the open-air treatment were practised by the Romans and the Greeks. Hypnotism was thought highly of by the priestly physicians in the temples of Isis in ancient Egypt. Perhaps one of the oldest forms of medication is organotherapy, which after a period of decline has again come into vogue. In medicine and surgery, as in all the arts and sciences, methods become general, then lapse into disuse, to be revived possibly at a later period and then to achieve a popularity which attaches to a supposed new thing.

THE QUEEN'S JUBILEE HOSPITAL.

THE simultaneous resignation of the majority of the members of the medical staff of a hospital always should afford material for inquiry, even though no difficulty should have been experienced in filling the vacancies thus created. It will be remembered that the Queen's Jubilee Hospital has of late been attracting attention and to those who are acquainted with its early history the marvel has been that the trouble has not made an earlier appearance. The initiation and the foundation were questioned from the first and many protests were raised against calling a new hospital into existence with a name which, though attractive, was scarcely warranted. The local need of the hospital was not apparent, since within reasonable distance a larger and better equipped hospital had been established for some years. Through all the appeals it was evident that the conception of the need of the hospital and of the suitability of its name originated with a general practitioner who was ready to contribute largely and to identify himself with the undertaking. In the natural course of events a medical staff became associated with him and a board of management was formed. The work has not, however, progressed smoothly and on Feb. 8th the late medical staff, with the exception of Mr. R. F. Benham and the dental surgeon, resigned, the new staff taking over the work on or about March 8th. On March 13th the chairman, Mr. G. R. Everitt, wrote to the authorities of King Edward's Hospital Fund, asking them to make inquiries "in connection with the recent trouble at this hospital and if possible to make arrangements for such investigation." Eventually Mr. Frederick M. Fry and Mr. J. Danvers Power were appointed to make an inquiry. Two visitors of the hospital—namely, Sir Thomas Smith and Mr. H. G. Smith—were also invited to serve on the inquiry but the former was unable to attend and the latter was out of England. Mr. Fry and Mr. Power held three sittings at the hospital, on April 6th, 7th, and 8th, and paid a visit of inspection on April 10th. The board of management was represented by Mr. Tom Green and Mr. Bavin and the late medical staff by Mr. R. P. Brooks, from whom, says the committee of inquiry, "we received every assistance." The report of the committee contains 23 clauses of which the last four are recommendations. The salient points of the report are as follows. As regards Mr. Benham it may be assumed that he continues to act on the staff for reasons personal to himself. "Unless these are connected with his recognised professional eminence, as distinct from academic qualifications, the only conclusion we can draw is that he occupies his position as a member of the medical staff in virtue of his being the founder of the [illegible] Should this be the case his position is a false one." [illegible] new staff the report says: "Individually and [illegible] new staff may have acted quite correctly for anything we can say to the contrary." The committee considers that the hospital has not been well conducted and that the old staff had not a free hand; that the board of management was not aware of many facts of which it should have had knowledge; and that the actual occasion of the resignation of the late medical staff "was not the best which might have been chosen." Further, "The charge against the ophthalmic surgeon we dismiss as unfounded. No corroborative evidence in support of the charges against the resident medical officer was brought before us." Clause 19 of the report states that in the opinion of the committee of inquiry a building on a large scale for in-patients is not required on the site of the hospital but that "as a casualty and out-patient department with a few beds attached, a properly constructed building might do useful work in the neighbourhood." The second recommendation runs as follows: "The advice we offer is that a period of, if possible, 12 months be placed between the present and the future permanent management of the hospital and that all the members of the present staff and board should resign, the treasurer and trustees continuing to perform their present duties." Another recommendation is that the governors should suspend the constitution, rules, and by-laws of the hospital for 12 months, and should elect, on the nomination of the executive committee of the King's Fund, a few gentlemen as a board of management to carry on the affairs of the hospital for that period under such temporary rules as they may find it desirable to frame. This board of management should be empowered to appoint, "with the approval of the Presidents of the Royal Colleges of Physicians and Surgeons if they should consent to give the matter their consideration, a medical staff to serve for one year." We can only hope that the governors and other authorities of the Queen's Jubilee Hospital will agree to abide by the recommendations of the committee appointed by King Edward's Hospital Fund.

RADIO-ACTIVITY AS A FACTOR IN HYDROTHERAPY.

SOME years ago, at about the time when argon and its equally inert colleagues krypton, neon, and xenon were discovered, we ventured to suggest that these elements owing to their occurrence in natural thermal waters might account, in part at any rate, for the value of these waters in the treatment of disease since it could hardly be supposed that a *few* grains per gallon of chalk, sulphate of lime, common salt, and so on could have any marked beneficial influence. The case is different with waters which contain a *notable* amount of salts, such as carbonate of soda or the aperient salts of soda and magnesia. The waters of Bath, Buxton, Contrexéville, and other places exhibit a comparatively feeble degree of mineralisation and yet there can be no doubt of their therapeutic value. Nor can it be supposed that a water which is naturally hot can have greater therapeutic effects than would be gained by the similar use of artificially heated water. So far, then, the findings of the physicist and the chemist do not afford a satisfactory hypothesis in regard to the therapeutic value of such waters. The question now arises whether the fact that these waters are radio-active will supply any explanation. Most, if not all, of the thermal springs in Europe which have been examined have been found to contain in slightly varying quantities argon and helium and in the majority of cases these waters have been found to be distinctly radio-active. Indeed, the presence of argon and helium would appear to be inseparable from radio-active properties. We seem here to be getting some light at length on what has long been an enigma, that of two waters showing the same chemical composition as regards their saline constituents the one of natural origin is distinctly superior therapeutically speaking to the one artificially compounded. The fact is that a natural water welling up from the earth is at the moment of its discharge from its source radio-active, while ordinary drinking water, rain water, well water, river water, and the like, do not generally exhibit this property to any extent. Further, since the property of radio activity is rapidly evanescent, the emanation quickly vanishing, it follows that if the benefit derived from undergoing a course of waters is due to the radio-activity of those waters the treatment should obviously take place near the source of the water—in other words, the waters should be used when they are showing a maximum degree of radio-activity. Some interesting remarks on this subject have reached us in the form of a pamphlet written by Dr. A. Piatot, consulting physician at Bourbon-Lancy (Saône-et-Loire) where there are thermal springs containing marked quantities of argon and helium and showing radio-active power. A geological exploration of the district has brought to light many radio-active minerals and the degree of radio-activity of the various hot springs in the locality would seem to vary apparently in direct accordance with the distance of the spring from its geological source. Dr. Piatot finds that the rule seems established in the case of the hot springs at Bourbon-Lancy that the least mineralised waters exhibit the most intense radio-activity and *vice versâ*. It appears to us that this interesting development of a theory of undoubted importance in hydro-therapy suggests a very simple line of research and the idea of radio-activity being the most important factor in "the course of waters" could be readily put to the proof. Radium baths could easily be prepared exhibiting a more powerful degree of radio-activity than that of the richest natural waters and their effects could be studied. The results would be certain to be most interesting.

ORGANS OF DIGESTION IN PITCHER PLANTS.

AN important and interesting paper was read at the general meeting of the Linnæan Society held on April 6th by Mr. W. Botting Hemsley, F.R.S., on the Pitchers of Nepenthes and at the same time many slides, prepared by Mr. L. Farmar, were exhibited illustrating the various types of pitchers and their curious glandular systems. The plants themselves are tropical and are widely distributed in the Asiatic Archipelago, from New Caledonia on the east to Sumatra and even to the Seychelles and Madagascar on the west. Borneo alone, which seems to be the head-quarters of the group, contains 20 species and Sumatra 10. They present some affinities to the aristolochiaceæ, sarraceniaceæ, and to the droseraceæ, of which our little sundew is the type. The pitcher is an appendage of the leaf, borne on a prolongation of the midrib which often acts as a tendril. It consists of a tubular or inflated body with two anterior longitudinal ribs, which often develop into elegant fringed wings, and one posterior rib, which usually terminates in a spur, running out just below the hinge of the lid or operculum. The mouth of the pitcher is surrounded by a more or less elaborately constructed collar or peristome. Glands are present on almost all parts of pitcher plants from the stems to the flowers. They vary much in structure but there are only two kinds, the attractive and the digestive. The attractive glands are generally distributed over the plant except on the inside of the pitcher where the digestive glands alone occur. Mr. Hemsley exhibited a new species which is characterised by the under side of the lip being thickly beset with stiff bristles interspersed with honey glands. The function of the bristles in this position is not obvious but their rôle would seem to be preventive to flying insects, though ants might creep amongst them and drink the honey. The honey glands are very prominent, oval or circular in outline, surrounded by a raised rim, and from one-fiftieth to one-twelfth of an inch in diameter. The digestive glands gradually increase in size from the lip downwards and vary in number from about 2000 to 5000 to the square inch. These glands are many-celled, ovoid or spherical in shape, and over-arched by the growth of the surrounding tissue, so that the surface is smooth to the finger stroking it downwards but rough in moving it upwards owing to the sharp edges of the arches. The arrangement of the parts in this and all the other species favours the descent of insects and other creatures into the pitchers but hinders their escape. The size attained by some of these leaves and pitchers is very great, those of the *Nepenthes rajah* having a total length of between five and six feet, whilst the capacity of the pitchers is as much as two quarts.

LAPAROTOMY IN A CASE OF ANGIO-NEUROTIC ŒDEMA OF THE INTESTINE.

WE have recently called attention to a case of angio-neurotic œdema with gastric symptoms in which the stomach was washed out and a piece of its mucous membrane came away in the fluid.[1] Microscopic examination showed, as had been previously supposed, that the gastric symptoms frequently present in angio-neurotic œdema of the skin are due to œdema of the mucous membrane of the stomach. In the *Boston Medical and Surgical Journal* of March 30th Dr. F. R. Harrington has recorded a most important case in which the small intestine was affected and laparotomy was performed and showed the condition of the intestine. A woman, aged 26 years, was admitted into the Massachusetts General Hospital. She had been admitted four times previously, twice into the surgical wards and twice into the medical wards. On the first occasion her symptoms suggested gall-stones but the subsequent course showed that they were due to an abdominal crisis of angio-neurotic œdema. Her first attack occurred at the age of 11 years and the swelling was confined to the hands and the feet. Attacks followed at decreasing intervals, the longest period of immunity being three months. In the last few years she never passed more than two weeks without an attack. The swellings extended up to the elbows but never above the ankles. The face was sometimes affected, becoming greatly œdematous from the eyes to the clavicles. The lips were swollen and eating was difficult, while the swallowing of liquids caused nausea. Sometimes swellings occurred on the scapulæ and the buttocks. Pain occurred in the lower abdomen and was accompanied by headache, nausea, and vomiting. As much as one or two quarts of green fluid were vomited at a time. During an abdominal attack the urine contained a trace of albumin and a few hyaline casts. Although angio-neurotic œdema was diagnosed the duration and the severity of the abdominal symptoms were thought to justify exploratory laparotomy during an attack. The stomach and the other organs were carefully examined but only the intestines showed anything abnormal. They were congested and so red that mild peritonitis was suspected. Near the ileo-cæcal valve was a cylindrical enlargement of the ileum two and a half inches long, with a circumference twice that of the rest of the intestine. The swelling was evidently in the wall of the bowel. To the touch it was elastic and did not pit on pressure. There was a good deal of clear fluid in the abdomen. Opinions may differ as to whether laparotomy was justified but the case is most instructive both pathologically and clinically. It is a warning to look for angio-neurotic symptoms in a case which may be thought to demand laparotomy. Professor W. Osler has emphasised this point in a paper on the Surgical Importance of the Visceral Crises in the Erythema Group of Skin Diseases.[2] He says: "The possibility of mistaking these visceral crises for appendicitis or intussusception or obstruction of the bowel and handing the patient over to the surgeon for operation is by no means remote." He relates three cases in which operation was performed and says: "The practical lessons to be drawn are, first, that in children with colic the greatest care should be taken to get a full history, which may bring out the fact of previous attacks, either of the skin lesions, of arthritis, or of intestinal crises; and, secondly, to make the most careful inspection of the skin for angio-neurotic œdema, purpura, or erythema."

MOTOR MANIACS.

THE motor-car is so useful and when properly driven so valuable a method of communication that no condemnation can be too strong for those who use it improperly. Two cases have recently been before the courts in which motor-cars were the cause of serious injury to persons who had just as much right to use the roadway as had the motor-car driver. In the one case, heard before the magistrates at Slough, George Harris Hendasyde of Edinburgh was committed for trial for feloniously slaying Mary Haines of Colnbrook. The woman was wheeling her baby in a mailcart along the narrow High-street of Colnbrook. She was in the roadway and as she was trying to turn the mailcart on to the pavement the accused's motor-car struck it. The woman, who held on to the handles, was turned completely over on to her head and fractured her skull. As the case is *sub judice* we have, of course, simply stated the facts which were given in evidence. In the other case, which was heard before the Wolverhampton magistrates on April 17th, Joseph Lisle was charged with recklessly driving a motor-car. Evidence showed that the defendant travelled along the Holyhead-road "at a tremendous pace" He ran into a cart drawn by a horse. The horse was killed, being practically smashed to pieces, and three occupants of the cart were seriously injured. The defendant, whose face was cut, was heard to say, "I was only going 60 miles an hour." The magistrates said that they had seriously considered whether they would not send the defendant to prison. However, they had determined not to do so but to fine him £50 and costs, to endorse and to suspend his licence, and to disqualify him from getting another licence for two years. On behalf of the defendant it was asked that the sentence might be suspended pending an appeal as Lisle was engaged to drive in the forthcoming Gordon Bennett cup trials. This, however, was refused and formal notice of appeal was given. Why the magistrates had any doubts as to sending the defendant to prison we cannot understand, but it would not be fair to go further than this confession of ignorance now that notice of appeal has been given.

THE CENTRAL PUBLIC-HOUSE TRUST ASSOCIATION.

THE report of the work accomplished by this association during 1904 shows that the movement in favour of the sale of food and non-intoxicants in public-houses is making good progress. The average licensed victualler looks upon the sale of beer and spirits as his principal, if not his only, object; his interest lies in making as much profit as possible and the customer who spends *most money* in the place is therefore the most welcome. The Central Public-House Trust Association, recognising the evils of this system, is in favour of "disinterested management" and the establishments conducted on the principles which it advocates are refreshment houses rather than mere drinking bars. Food as well as non-intoxicating drinks, including tea, coffee, and cocoa, are served as a matter of course. The houses are managed by men who receive a fixed salary and have no interest in the profits arising from the sale of intoxicants but are entitled to a percentage on the profits made by the sale of foods and non-intoxicants. To carry these principles into effect trust companies have been established in various parts of the United Kingdom, the number of such companies registered at the end of December, 1904, being 35 in England, one in Wales, and one in Ireland. In Scotland, where there is a central association under the presidency of Lord Balfour of Burleigh, there are four district trust companies and 14 companies for the management of single public-houses. The total number of public-houses under trust management is 170. Two of these are in London—namely, the "Duke of York," High-street, Shadwell, E., and the "Waterman's Arms," Bankside, S.E., not far from the Surrey end of Blackfriars Bridge. Wherever new working-class residential districts are being developed and it is decided that a licensed house is necessary for the convenience of the public, the owners of the property are urged to enter into negotiations with a trust company to acquire a site and to apply for the new licence rather than to allow the establishing of a "tied house," which is practically the only alternative. The Earl of Lytton is president of the association and Colonel Sir Colin Scott Moncrieff is chairman of the executive committee. The offices are at 116, Victoria-street, Westminster, London, S.W., where a variety of literature relative to the liquor traffic may be obtained. The secretary of the Scottish Association is Mr. J. F. Roxburgh, W.S., 23, Rutland-square, Edinburgh. The Duke of Westminster has lent Grosvenor House, London, W., for the meeting of subscribers to the association to be held on May 23rd at 3 P.M. The Earl of Lytton will be in the chair.

THE MEDICAL MAN, THE CORONER, AND THE PATHOLOGIST.

Two inquests recently concluded by Mr. Troutbeck within a few days of one another illustrate the attitude which he has thought fit to adopt towards the medical profession with regard to the employment of Dr. L. Freyberger for the performance of post mortem examinations within his jurisdiction, although they scarcely appear to afford examples of the policy which the London County Council has claimed to have adopted in sanctioning the innovation. This policy we understood to be based upon a supposed incompetency on the part of the general medical practitioner to hold necropsies of a trustworthy character, particularly in instances where the cause of death might possibly be obscure, the lack of practice in such matters on the part of the average medical man and difficulty occasionally arising being dwelt upon by those advocating the methods followed by Mr. Troutbeck. It has also been suggested that at times the medical man who had attended the deceased might be desirous of concealing an error in diagnosis or treatment and so might be tempted into a lack of candour as to what the post-mortem examination actually revealed. Turning to the two inquests to which reference has been made above, we observe that in one case death was the result of an abortion criminally produced. Both drugs and instruments were spoken of at the inquest as having been mentioned by the deceased woman as the means used upon her, but no trace of the latter agency was found by Dr. Freyberger. This case may well rank as one of importance in which exceptional care and skill would be desirable on the part of whoever performed the post-mortem examination. In the other, however, when we seek to bring it into the same category, we find that as to the manner of death there was no question. A small boy, nine years of age, had been run over by an "electric landaulette," the driver of which was present to admit that the occurrence took place, and the post-mortem examination, again held by Dr. Freyberger, showed that death was due to "fracture of the neck and laceration of the spinal cord and that the liver was found to be torn into six pieces." We can hardly believe that special skill and experience on the part of the pathologist can be necessary to assign the cause of death after a person has been run over by a motor-car, or that the evidence mentioned above would support such a contention. We find it difficult to trace a policy aiming consistently at efficiency in Mr. Troutbeck's actions. The death to which we first referred took place in the Westminster Hospital, the second one in St. George's Hospital. At these two institutions there are gentlemen whose evidence would be at least equal in value to that of Dr. Freyberger as to the post-mortem evidence either of criminal abortion or of the injuries caused by a motor-car. Curiously enough we find that a third inquest was recently held in which the deceased died in St. George's Hospital as the result of being run over by a hansom cab, and in this case apparently all the medical evidence as to the result of the post-mortem examination was given by the house surgeon. We continue to think that until the legislature provides differently the Coroners Act, 1887, as far as it is applicable, should regulate these matters and to be doubtful whether any possible alteration in the law should follow the lines indicated in the city of Westminster and in the south-western district.

THE VISIT OF BRITISH PHYSICIANS AND SURGEONS TO PARIS.

WE are asked to state that the expense of the excursions to Vichy, Evian, and Salies de Béarn in connexion with the visit of British physicians and surgeons to Paris will be entirely defrayed by the *municipalities of the three* famous watering-places. Intending visitors to Paris should notify to the honorary secretaries of the London Executive Committee, Dr. Dawson Williams, 2, Agar-street, Strand, W.C., and Dr. W. Jobson Horne, 27, New Cavendish-street, Portland-place, W., before Friday, April 28th, which excursion they would like to take part in. Any practitioner who has accepted the invitation and has not received a circular from the London executive committee this week should communicate with one of the honorary secretaries. We may add that the honorary secretaries have no further information with regard to the concessions which the South-Eastern and Chatham Railway and the Nord Company of France are willing to make for the journey from Charing Cross to Paris and back, but Dr. Boyd B. Joll, 8, Hanger-lane, Ealing Common, W., has ascertained that the companies controlling the Newhaven and Dieppe route will grant excursion rates to a party of not less than 30. Communications should be addressed to him. The Paris committee expects to be able to arrange a visit to Bagnoles de l'Orme on the return journey for those who choose this route.

A RECOGNITION OF GOOD WORK.

ALL who work will feel that there is no reward of their services equal to that of right appreciation and the expression of confidence from those with whom they work. Mr. Samuel Osborn, F.R.C.S., who has for many years been the chief surgeon to the Metropolitan Corps of the St. John Ambulance Brigade, has just been made the recipient of a testimonial, of which he has every reason to be proud. It consists of two portions, the one a silver bowl with the following inscription :—

> Presented to Samuel Osborn, Esq., F.R.C.S., District Chief Surgeon (No. 1 District) St. John Ambulance Brigade, by the Honorary Surgeons of the District as a small token of their esteem.

The bowl was presented on April 12th, at the headquarters, St. John's Gate, Clerkenwell, on behalf of the honorary surgeons, by Honorary Surgeon J. Bremner, who was introduced by Honorary Surgeon M. K. Hargreaves. Besides the bowl the following address, signed by over 50 of the honorary surgeons, was presented to Mr. Osborn :—

HON. SURGEONS OF THE ST. JOHN AMBULANCE BRIGADE.
METROPOLITAN CORPS.

This Testimonial was presented to Chief Surgeon S. Osborn, F.R.C.S., by the Hon. Surgeons of the Metropolitan Corps of the St. John [illegible] trust that he may long be spared to continue his esteemed services, and give his ripened experience to the cause of the St. John Ambulance Brigade.

We join in offering our congratulations to Mr. Osborn upon a worthily deserved recognition of his work.

THE medical officer of health of the Cape Colony states that for the week ending March 25th the condition of the Colony as regards plague was as follows. At East London 3 cases of plague were discovered, occurring respectively in a native male and 2 European males. Plague-infected rodents were found both at East London and at Port Elizabeth. In other districts no case of plague occurred in man or in other animals.

THE Jacksonian prize has been awarded by the Council of the Royal College of Surgeons of England to Mr. Herbert J. Paterson, M.B. Cantab., F.R.C.S. Eng., for his essay on "The Diagnosis and Treatment of such Affections of the Stomach as are amenable to Direct Surgical Interference."

THE annual dinner of the Pharmaceutical Society of Great Britain will be held in the Whitehall Rooms, Hôtel Métropole, London, on Tuesday, May 16th, at 6.45 for 7 o'clock P.M. precisely.

SOME CONSTITUENTS OF VIOLET LEAVES.

WE are not advocating violet leaves as "a cure for cancer." We have not advocated violet leaves as "a cure for cancer." It is probably quite unnecessary to tell our readers these things, but we do so in the hope that through them the false impression of the public may be removed. We recently published a note upon a case where a patient who may have been suffering from malignant disease was apparently relieved of the symptoms, and where an application of violet leaves had been employed. The note was signed by a medical man. On the strength of this certain reckless lay papers have spread the news that THE LANCET advocated violet leaves as "a cure for cancer." We have been congratulated by journals that give prominence to quack preparations upon our breadth of view and we have been inundated with letters from unfortunate persons who have been cruelly deceived by the gross misrepresentation of our position in the matter. It seems now quite impossible to get ahead of the falsehood so circumstantially detailed and so widely circulated; we have therefore decided to make an investigation into the active principles of the violet to which we can refer the medical profession when they are worried with inquiries as to our views on the influence of this plant as "a cure for cancer." The report from our laboratory is as follows:—

A search for active principles is at once suggested when it is assumed that a drug possesses a specific therapeutic action. The result may be to raise *empirical to the level* of rational treatment but it cannot be said that in every instance the discovery and the recognition of active principles have given any closer insight into the action of drugs from which these principles have been separated in a more or less pure form. Digitalis, for example, is the chief active principle of foxglove but why a glucoside of this particular composition should so powerfully affect the heart it is difficult to say. Its pharmacology may be clear but its physiological action is by no means easily explained on the basis of its composition. The glucosides are, in fact, a very interesting group of bodies, for in many instances the members of the group exercise a powerful physiological action and they are not in any way related to alkaloids nor do they contain in general a nitrogen nucleus but consist apparently of a glucose radicle combined with a hydrocarbon group. The glucosides may be viewed as compound ethers yielding on hydrolysis, as by the agency of a ferment or of a dilute acid, glucose and another substance not belonging to the class of carbohydrates. Salicin, for example, gives glucose and saligenin on boiling with dilute sulphuric acid. Digitalin, however, does not appear to yield sugar but other products which contain carbon and hydrogen. Amygdalin is a rare example of a gluc[illegible] up into [illegible] evident, [illegible] physiolo[illegible] of hydrolysis.

According to a recent investigation conducted in THE LANCET Laboratory the fresh green leaves of the violet yield an abundance of a crystalline glucoside when suitably treated. They also yield a definitely crystalline body which behaves—chemically, at any rate—as an alkaloid. The pharmacology of the violet leaf is therefore interesting. The common violet (*viola odorata*) belongs to the group of violaceæ, of which the viola tricolor, or pansy, and ipecacuanha are members also. The pansy contains an emetico cathartic principle called violin. The fluid extract is said to produce a sense of confusion and dulness in the head, with headache; some dimness of vision, salivation, vesical tenesmus, with frequent and profuse micturition; turbid urine, offensive to the smell; and a sense of heat over the whole body, sweats, itching, and nettle-rash. [illegible] the second stage with serous or sero-purulent exudation and crusting. The medicinal virtue is said to reside in the leaves of the pansy plant, and it is the leaves of the violet which have been employed in cancer. We found that on extracting 100 grammes of the fresh green leaves of the common violet with boiling water and after removal of extraneous substances (pectose, &c.) by means of acetate of lead and subsequent removal of the lead by sulphuretted hydrogen a yellowish coloured solution was obtained which on evaporation yielded a dark-coloured treacly mass. It was possible to decolourise the solution with animal charcoal but on exposure to air the colour quickly returned. On placing the sticky mass in vacuo over concentrated sulphuric acid crystals were obtained—some were stellate and feathery, some silky, and others in needles. The yield was about 2 per cent. In this residue no evidence of the presence of an alkaloid was obtained. A solution of the mass was found to reduce alkaline copper solution but the reduction was very much more marked after the solution had been boiled for a few minutes with dilute sulphuric acid. Further, a solution of the crystals yielded no osazone until after treatment similarly with acid.

These results point to the presence of a glucoside and the amount of glucose yielded on hydrolysis was as much as 33 per cent. of the total extract. Alcohol, however, was found to be a much more effective solvent and accordingly 200 grammes of the fresh green leaves were boiled with alcohol under a reflux condenser for several hours the leaves were strained off, a [illegible] to dryness [illegible] was filtered, [illegible] the water bath. A similar treacly residue was [illegible] which yielded an abundance of crystals when placed in vacuo over strong sulphuric acid. The crystals consisted of silky needles, some were star-shaped and others were feathery masses. There was again no evidence of an alkaloid in these crystals but on hydrolysis they yielded an abundance of glucose to the extent of about 33 per cent. The alcohol extracted furthermore a good deal of dark green oil similar in appearance to apiol or oil of parsley. This oil was shaken with acidulated water and the liquid was filtered. On evaporation a small residue of star-shaped and feathery crystals was obtained which gave reactions common to alkaloids. In particular an abundant crystalline precipitate was obtained with iodine solution in potassium iodide and with Millon's reagent. A yellowish colour was given with strong sulphuric acid, a reddish-brown with nitric acid, and a greenish colouration with molybdic acid and sulphuric acid. It was then thought desirable to extract the spent leaves—i.e., after they had been extracted with alcohol—with chloroform, the whole mass being made alkaline and pasty by adding magnesia. A certain amount of green oil was thus extracted which remained as a residue after evaporation of the chloroform. The residue was then made slightly acid with hydrochloric acid and water was added. After heating separate quantities of the fluid were filtered and evaporated to dryness in vacuo over strong sulphuric acid. A small but distinct cluster of star-shaped crystals was obtained which was decidedly bitter to the taste and which gave very good general reactions for alkaloids. It would thus appear from this preliminary and, perhaps, somewhat cursory investigation that the violet contains two distinct crystalline principles, a glucoside and an alkaloid, and, in addition, a dark green oil. The glucoside amounted in these experiments approximately to 2 per cent. of the leaves, the oil to 0·3 per cent., while it was not possible to say what quantity of alkaloid was present as the amount yielded was so small. It is, however, interesting to record that the alkaloid from violet leaves behaved chemically much in the same way as emetine, the principal alkaloid of ipecacuanha. We hope to pursue the study and as soon as more material is procurable to extract a tangible quantity of the alkaloid in order to throw more light on its nature and possibly on its composition.

As some proof of the extent to which our mythical words have led to misunderstanding it may be added that we had some difficulty in obtaining a good supply of violet leaves in London, a brisk demand having arisen for them owing, as one vendor in Covent Garden market remarked, "to a fad started by the medical journals about violet leaves being a cure for cancer." We must again dissociate ourselves from this fad. We are not advocating violet leaves as "a cure for cancer." We have not advocated violet leaves as "a cure for cancer."

SIXTY-SIXTH ANNUAL REPORT OF THE REGISTRAR-GENERAL FOR 1903.

II.

IN a previous notice[1] of the Registrar-General's recently issued report we reviewed in general terms that section which treats of the part played by meteorological conditions as a factor of the exceptionally low mortality of the year 1903, special attention being directed to the influence of those conditions on the vitality of the infant part of the population. On the present occasion we propose to consider as fully as space permits the incidence of those particular forms of disease the greater or less fatality of which determines the total mortality in a given time or place.

A commendable feature in the present series of reports is this—that not in the tabular portion alone, but equally in the accompanying commentary, the same general arrangement that characterised the first number of that series has been consistently maintained in the numbers issued subsequently. Especially valuable to those seeking information on a particular subject is the alphabetical index, which has evidently been compiled with much care and which will be found at the end of the volume.

As regards the prevalence of small-pox we learn that although the mortality directly ascribed to that disease in 1903 was only one-third of that of the previous year, nevertheless chicken-pox is stated to have claimed a considerable number of victims. Many of these deaths, however, were almost certainly due to unrecognised small-pox.

In proportion to the number of children living at those ages who are especially liable to these diseases the deaths from measles, scarlet fever, whooping-cough, and diphtheria were considerably below the average. The mortality from the several infectious diseases of children is conveniently shown in Table K which appears in the section of the report dealing with mortality at that time of life. From the general tables in the appendix it appears that diphtheria accounted for a considerably lower general mortality than in any year since 1891. But although in at least 11 counties, including London, this disease was less fatal in 1903 than in the quinquennium immediately preceding, there were still 16 populous English counties wherein the mortality was above that of extra metropolitan England. For several years past an extensive area, including parts of Monmouthshire and South Wales, has been indicated as suffering excessively from diphtheria. In the year 1903 this area was somewhat contracted, but the mortality was still very high in a continuous district mainly included in the former area, and consisting of the unions of Crickhowell in Brecknockshire, of Abergavenny and Bedwellty in Monmouthshire, and of the entire county of Glamorganshire excepting the district of Gower; the diphtheria death-rate in this contracted area amounted to not less than 342 per 1,000,000 of its aggregate population, which is little short of double the rate prevailing in the country generally. Enteric fever accounted in 1903 for a mortality that was the lowest on record. This disease is much more fatal in the town than in the country, not in one year only but on the average of a long series of years. The loss of life is greatest among males, the corrected death-rate being 120 per 1,000,000 for that sex, against only 82 per 1,000,000 for females. Between the ages of 15 and 35 years this disease is particularly fatal. In both sexes the mortality is low in children under five years, after which age it gradually increases to a maximum and thereafter gradually declines. At ages above 65 years the mortality does not greatly differ from that of childhood, the rate at the former age varying from 30 per 1,000,000 in the country to 45 in the town. Among counties with populations exceeding 100,000 the West and North Ridings of Yorkshire and the counties of Lancaster, Glamorgan, and Carmarthen suffered most severely in 1903, the mortality ranging from 135 per 1,000,000 in the first-named county to 184 per 1,000,000 in the last. The mortality from pneumonia fluctuates considerably from year to year. According to the general tables the fatality of that disease appears to have increased in recent years. Some of this increase is unquestionably due to the simultaneous prevalence of influenza, which disease has contributed largely to the death roll, both directly and indirectly, ever since the autumn of 1889. In the year 1903, however, a significant fall took place in the mortality from pneumonia, as well as from bronchitis, a fall which is much greater than that recorded under the head of influenza and apparently independent of the latter. It is in populous communities more particularly that the various types of pneumonia are destructive to life, the table showing an excess of 90 per cent. in the death-rate of the urban as compared with that of the rural districts. The sexes fall victims in unequal proportions, the male rates being in excess of the female by 50 per cent. Childhood and extreme old age are the periods chiefly vulnerable by this disease, the mortality under five years averaging five per 1000 living at that age and the mortality at ages over 65 years averaging 3·5 per 1000 then living. The fall in the mortality from tuberculosis which had been recorded for many past years showed no diminution in 1903. But inasmuch as this disease in one or another of its forms still contributes at least 11 per cent. to the total mortality and accounts for a death-rate of 1742 in each 1,000,000 of the population, medical interest in its ravages continues unabated. Of the total deaths from tuberculous disease nearly 70 per cent. are attributed to "phthisis" and although there is reason to doubt the accuracy of diagnosis as regards some of the deaths thus returned in the "fifties" and "sixties" it is certain that in recent years, at all events, the deaths somewhat indefinitely ascribed to "phthisis" are in reality for the most part due to tuberculous infection. The mortality from pulmonary tuberculosis in 1903 was at the rate of 1427 per 1,000,000 living at all ages among males and at the rate of 993 per 1,000,000 living among females; the mortality of the male sex was therefore greater than that of the female by 44 per cent. As compared with the average in the previous five years the male rate was lower by 93 per 1,000,000 and the female rate lower by 98 per 1,000,000 of the respective populations. Among males the rate was much higher in the town than in the country, whilst among females the difference was inconsiderable.

---

[1] See THE LANCET, April 1st, 1905, p. 880.

When the 40,000 annual deaths from pulmonary tuberculosis are distributed according to age as well as to sex certain peculiarities appear which are not otherwise noticeable For example, although the mortality for persons at all ages in 1903 was below the quinquennial average the fall was practically limited, in the case of males only, to the ages under 55 years Taking the average rates in the five years ended with 1902 it will be found that this disease was more fatal in the urban counties than in the rural, with the exception that among males aged 15-25 years and among females aged 5 35 years the rural mortality was the highest These exceptions are remarkable and are worthy of serious consideration by those who are particularly interested in the public health

The age of maximum mortality may be stated generally as follows In England and Wales as a whole and also in the urban districts it is at 45-55 for males and 10 years earlier for females, in the rural districts it is 35-45 for both sexes The local distribution of fatality from this disease varies enormously, in fact, the difference is so great as to suggest that in some parts of this country the causes of death may be certified less carefully than they should be The present report shows that after adequate allowance for age differences among the living this disease was extremely fatal in South Wales, the death rates in Carmarthen, Pembroke, and Cardigan averaging 1855 per 1,000 000 for males and 1601 per 1,000,000 for females In parts of North Wales also the disease was more destructive than elsewhere, the average female death rate in the counties of Merioneth, Carnarvon, and Anglesey being especially noteworthy and amounting to 1705 per 1,000 000 living of that sex a rate which is not less than 72 per cent above that of England and Wales generally If the mortality from pulmonary tuberculosis be contrasted with that from pneumonia it will be found that whereas the former disease selects its victims mainly from among adolescents and young adults of both sexes—that is to say, from that portion of the population which is economically the most valuable to the community—the latter disease, on the other hand, is fatal for the most part either in infancy or in extreme old age It is this peculiarity in the age incidence of pulmonary tuberculosis that invests the disease with an importance which otherwise it would share only in common with other large contributors to the death roll

Referring yet again to that section of the report which treats of mortality at the earlier ages we learn that in every 1000 children living below the age of five years between three and four are annually sacrificed to tuberculosis, chiefly to the [illegible] tion The death [illegible] less numerous [illegible] and 7000 annually, nearly 70 per cent of which are those of children at this early age Boys under five years succumb to this disease in greater proportion than do girls, a peculiarity that attaches to other forms of tuberculosis likewise

Equally destructive to child life is tuberculous peritonitis a disease which, in spite of the protests of the authorities at Pall Mall, is still often miscalled tabes mesenterica It remains doubtful what proportion of the deaths referred to the latter cause are really tuberculous in character, although the age distribution of the deaths thus returned does not differ greatly from that of the deaths definitely attributed to tuberculous peritonitis Rheumatic fever is a disease that has attracted greatly increased attention from medical men since its infective nature has become generally recognised Since 1901 rheumatic fever has been distinguished in the national records from those forms of chronic valvular disease that depend on antecedent acute rheumatism This arrangement will facilitate the study of rheumatic fever as soon as the data for a considerable number of years are available Meantime, the following facts have been definitely ascertained concerning the incidence of the disease first that fatal cases of it are frequent at all stages of life, and secondly, that although at ages below the fifteenth year girls suffer more severely than boys at ages above the twenty fifth year, the mortality is generally highest among men The only serious exceptions to the rule that the mortality of this country in 1903 was lower than that of recent previous years are furnished by cancer and diabetes mellitus If the deaths from malignant disease are calculated on the aggregate population the disease would appear to have exacted a death toll of 732 per 1 000,000 among males and of 1003 per 1,000 000 among females These rates are the highest on record We have previously remarked, however, that the crude rate of cancer mortality is misleading for comparative purposes because of changes in the age constitution of the living But if instead of computing the mortality at all ages we apply the deaths at ages above 35 years to the number then living we obtain the ratio at that stage of life in which cancer is most fatal, and the result duly corrected for age differences in the living is fairly comparable as between different periods or different localities Calculated in this manner the deaths from cancer in the year 1903 were equal to a rate of 2247 per 1,000,000 males and 2958 per 1,000 000 females living at ages above 35 years, the rates in the preceding five years having averaged 2074 and 2866 per 1,000 000 respectively From diabetes mellitus there has been an increase in the total death rate but this increase has affected females exclusively, the mortality among males having shown a slight decline, whilst that of the other sex has increased by 19 per cent as compared with the quinquennial average Inasmuch as 70 per cent of the total mortality occurs at ages above 45 years the disease is evidently one of advanced life

ROYAL COLLEGE OF SURGEONS OF ENGLAND

A QUARTERLY meeting of the Council was held on April 13th, the President, Mr JOHN TWEEDY, being in the chair

In accordance with the recommendation of the Jacksonian Committee the Council awarded the Jacksonian prize to the author of the dissertation on the Diagnosis and Treatment of such Affections of the Stomach as are Amenable to Direct Surgical Interference, bearing the motto, "Work and Despair Not' The PRESIDENT proceeded to open the envelope bearing this motto and declared that the name written therein was H J Paterson, F R C S, M B, B C Cantab It was resolved that Mr Paterson should be requested to attend the ordinary meeting of the Council in May to receive the Jacksonian prize

In accordance with the recommendation of the Jacksonian Committee the following subject was chosen for the Jacksonian prize for the year 1906 "The Diagnosis and Treatment of those Diseases and Morbid Growths of the Vertebral Column Spinal Cord, and Canal, which are Amenable to Surgical Operations

The PRESIDENT on behalf of himself and the Vice Presidents, reported the delivery of the following Hunterian lectures—viz three lectures by Mr P Lockhart Mummery on the Physiology and Treatment of Surgical Shock and Collapse, three lectures by Mr W Sampson Handley on the Dissemination of Mammary Carcinoma, and three lectures by Mr Clinton T Dent, two on Congenital Hypertrophic Stenosis of the Pyloric Canal and one on the Forms of Softening and Fracture of the Bones occurring in Childhood and Youth

The PRESIDENT reported, on behalf of himself and the Vice-Presidents that Mr Donald J Armour, Arris and Gale lecturer had duly and properly delivered a course of three lectures on the Anatomy Physiology, Pathology, and Surgery of the Gasserian Ganglion

A report was received from the committee on the proposed institution by the College of a medical school The report was adopted its main features were as follows It was proposed that the school should provide for the teaching of the earlier subjects—viz, chemistry, physics, and biology—and also the intermediate subjects—viz, anatomy and physiology—and it was suggested that with the concurrence of the Royal College of Physicians of London the Examination Hall buildings with the addition of a storey on the front portion might be used for the purpose This arrangement would provide for about 100 students The scheme was considered with a great deal of care and estimates were prepared of the annual cost of such a school From these estimates it appeared that the additional annual cost would be about £4400 after the first two years The committee was of opinion that it was impracticable for the College to institute such a school without adequate endowment

A report was received from the discipline committee referring to several cases and the Council directed that action should be taken in accordance with the recommendation of the committee.

Mr. H. T. Butlin was re-appointed the representative of the College on the Senate of the University of London for a period of four years.

The Council was informed that by the will of the late Mrs. Begley, the widow of Dr. William Chapman Begley, M.R.C.S., there was a bequest of £20 per annum to the College for the purpose of founding a studentship in anatomy and surgery. The Council expressed its willingness to take steps to give effect to Mrs. Begley's wishes.

A letter was read from Mr. W. F. Dearden, honorary secretary of the Association of Certifying Factory Surgeons. It called attention to the proposition contained in the Accidents (Mines and Factories) Bill now before Parliament, to abolish the present statutory requirement placed upon the certifying surgeon to investigate such accidents occurring in factories and workshops as are caused by machinery in motion, explosion, escape of gas, &c., and to substitute a discretionary power with the local factory inspector, who will decide from a perusal of a filled-up notice form sent in by the employer what accidents require a surgeon's investigation. The letter invited the consideration of certain points and asked the College if it should consider the subject to forward the result of such consideration, if in agreement with the contentions of the association, to the Secretary of State for Home Affairs. It was felt by the Council that this was a matter of administration which hardly came within the scope of the functions of the College.

ALCOHOL AND PHYSICAL DETERIORATION.

UNDER the auspices of the Leicester Medical Society, the Leicester division of the British Medical Association, and the Leicester Medical Union a conference of medical men from the town and county of Leicester was held recently at the Leicester town-hall. The chair was taken by Mr. R. C. STEWART (President of the Leicester Medical Society) who introduced Professor G. Sims Woodhead who had been invited to deliver an address upon the Relation of the Use of Alcohol to Physical Deterioration.

Professor SIMS WOODHEAD said that alcohol was one of the great predisposing factors in disease and one of the great factors in preventing physical improvement. It was a potent cause of degeneration not because of its rapid action but because of the changes that it produced in the system, in the first place directly and in the second place indirectly. It was now recognised that alcohol did not act as a stimulant for more than a very short period, if, indeed, it acted as a stimulant at all, but that it acted as a paralysing agent. Even in comparatively small quantities it interfered with the functional activity of the cells. It acted first of all upon the nerve cells, which were the most highly developed in the body and their full functional activity was necessary for the carrying on of the vital processes of the body. If a working man interfered with the perfect health of his nerve cells he became of less value as an individual and to the community and there was a danger of deterioration in his family. It was not the mere actual loss of the money spent in drink but the deterioration of his physical condition which made him of less value in maintaining his family. In the report of the Inter-Departmental Committee on *Physical* Deterioration the committee always came back to this point: That by getting rid of alcoholism it would be possible to get rid of a great many of those social conditions which appeared to be at the root of much of the degeneration of certain nations and which appeared to prevent more rapid development of others. It had found that if there was a large amount of alcohol taken in any community the amount of physical deterioration was always great; and it also found that if that amount diminished the physical condition invariably improved. It found, for example, that England was in danger of the same evil that faced France at the present time. So long as the men only drank there was no such very marked deterioration but as soon as the women began to drink there was first of all a large increase in the number of infants with unstable nervous systems and in the number of deformed children. Ultimately the women became barren. In France since 1830 there had been a gradual upward trend in the consumption of spirits and there had coincidently been an increase in the consequences of drink, such as accidental deaths, suicides, and lunacy; there had also been a definite increase in the percentage of conscripts refused as unfit for service. In Sweden matters were just the reverse. Since 1830 there had been a great diminution in the amount of spirits drunk in Sweden and there had been a corresponding decrease in crimes, suicides, and deaths from syphilitic diseases; the percentage of conscripts refused had also been steadily reduced. With regard to the medicinal use of alcohol he did not say that there were not certain specific conditions, certain temporary symptoms, when alcohol might do good, but there were other drugs which were fully as efficient.

Mr. STEWART said, speaking for himself, that he agreed with Professor Sims Woodhead entirely in what he had said. For some years past the use of alcohol by the medical profession had been steadily declining. He saw some remarks of a bishop the other day in which his lordship congratulated temperance societies on the work which they had done and he added that one of the most hopeful signs was the conversion of the medical profession on the subject of alcohol. He (Mr. Stewart) rather thought that the medical profession had been going on rather quietly in this matter and, without advertising themselves, had for a considerable time past been giving patients less and less alcohol. So far as asylums went nearly all such institutions in England were giving up alcohol as an article of diet. He had persuaded the committee at his own asylum to do this, but although this happened two years ago the committee still kept asking him how the patients got on without it. He always replied that they got on much better without it, especially the epileptics. Out of 284 patients now in his asylum he was only giving alcohol in the form of medicine to two. Another thing was that if alcohol was given he insisted upon it being given with a meal. When he was appointed to the asylum 20 years ago alcohol was prescribed very largely. Whisky and water and port wine were given at all times of the day. They had tried the experiment of doing without alcohol in many asylums and he thought everybody was agreed that the patients were quieter and received greater benefits without it.

Dr. C. KILLICK MILLARD (medical officer of health of the borough of Leicester) said that in cases of scarlet fever it was not the medical man who cured the patient but nature and the best thing that they could do was not to interfere with nature. He was afraid that in the past medical men had not been so much the handmaid of Nature as ought to have been the case, but he believed that at the present time there was hardly a fever hospital in the country in which alcohol was prescribed.

Professor SIMS WOODHEAD, in reply, said that he was very glad to hear Mr. Stewart say what he had with regard to the medical profession, because it gave him the opportunity to accentuate the fact that medical men at the present time were doing more for temperance work than any other single body of men. That was an exceedingly important point, because their opinion on such a subject was valued and a patient would take the advice of a medical man when he would not take it from anyone else. Proceeding, Professor Sims Woodhead remarked that but for syphilis and alcoholism the asylums of the country would be comparatively empty.

Dr. F. M. POPE proposed a hearty vote of thanks to Professor Sims Woodhead for his address. He said that anyone who had practised medicine for any length of time must have noticed the diminution in the amount of alcohol prescribed directly as a drug. He (Dr. Pope) had the utmost pleasure in saying that he could support everything which Professor Sims Woodhead had said in the direction of the undoubted benefit this had been to medical science. His own view was that they should treat alcohol in the same way as any other drug. They should first satisfy themselves that it was essential and necessary and then it should be given in absolute definite doses. Thirdly, the duration of the time during which the drug should be given should be absolutely in the physician's discretion and should not be exceeded in any circumstances.

Mr. G. C. FRANKLIN, in seconding the motion, said that he was not an old man but he remembered the time when alcohol was declared to be of value in certain diseases, particularly in the treatment of phthisis.

The motion was carried *nemine contradicente.*

Professor SIMS WOODHEAD briefly acknowledged the compliment and the proceedings then closed.

MEDICINE, ITS PRACTICE AND ITS PUBLIC RELATIONS.

CHAPTER VIII.[1]

THE NAVAL AND MILITARY MEDICAL SERVICES (*continued*).

The Indian Medical Service.—The Old Grievances and the New Warrant.—The Language Examination.—The Treatment of the Civil Side: Bad Pay.—The Naval Medical Service.—Reorganisation and Redress.—The Need of Further Reform.—General Considerations.

IN the Naval Medical Service and in the Indian Medical Service, as in the Army Medical Service, we have to consider new conditions of employment designed to meet a growing reluctance on the part of medical men to join the services.

The Indian Medical Service.

New regulations for the Indian Medical Service were issued early in October, 1903. An admirable service in the past, the Indian Medical Service at no time fell from its estate to the depth that we have seen occur in the case of the Army Medical Service. But the Indian Medical Service had manifest grievances which were fast altering its status in the eyes of the medical profession when the new warrant was issued. Complaints were rife which showed that unless measures of reform were granted the splendid service to which India owes so much, and to which our Crown owes so much, was in peril of finding no men to hold its commissions. To begin with, the pay in the Indian Medical Service was poor, inferior to that of the Army Medical Service in almost every instance. Whilst the latter Corps offered to the senior medical officer in charge of a hospital charge allowance at generous rates, and specialist pay in certain cases, no similar allowances were received by the Indian officers. For a long time it had been stated that a corresponding increase of pay to that granted to the Army Medical Service would be given to the Indian Medical Service but the matter remained perpetually "Under consideration." The low pay was the first grievance. Secondly, when an officer of the Indian Medical Service was given an appointment bringing in increased emoluments he had to pay his own passage money to take it up. Thirdly, an officer could only draw the lowest rate of pay until he had passed the language examination, but owing to the frequent moves of junior officers on first landing in the country it was often impossible for them to pass this examination for some time. Fourthly, the emoluments on the civil side, which used to be an alluring factor of the Indian Medical Service, had diminished considerably. Chiefly owing to the increasing number of trained and well-qualified native practitioners—men trained, moreover, at the hospitals manned by the Indian Medical Service—there became less scope for practice, while a limitation of private fees by the Government of India, which many regard as both unfair and objectionable, also reduced the income looked forward to by men in civil employment. Lastly, as regards promotion, a lieutenant-colonel at the age of 55 years was bound to retire on a pension of £500 a year (unless promoted) for 25 years' service and on £700 a year for 30 years' service in similar circumstances. But owing to the diminution of administrative posts that succeeded the amalgamation of the military medical administration of the two services in 1880 there was practically no chance of a lieutenant-colonel of 25 years' service coming up for selection for an administrative post. He thus had to retire upon £500 a year, whereas if he had succeeded to an administrative post he would have earned a pension of £700 by the time he had passed through his term of office, plus the additional £250 a year for the holding of such posts. He lost, in fact, £450 a year as compared with former years. This is a brief summary of the grievances which awaited redress in the Indian Medical Service before the issue of the new warrant.

The new warrant at once adjusted to a substantial extent the irregularity of pay between the two military medical services. The financial condition of the Indian medical officers, as far as concerns the military department, is now much better. The minimum sum which a lieutenant now receives after arrival in India is Rs.420 a month, the equivalent, with the exchange compensation, of £357 a year, while the officer who never aspires to anything beyond the charge of a regiment and who serves for over 25 years will in future draw Rs.1300 a month, which is equivalent to over £1100 a year. To these rates of pay every man who enters the Indian Medical Service may confidently look forward, for paragraph 9 states that "a major is promoted to lieutenant-colonel on completion of 20 years' full pay service"—there is to be no selection for that rank to which every officer who serves long enough will attain. But while the pay is generally improved the remuneration of the administrative posts remains the same save that the pay of the Director-General is increased.

Specialist pay of Rs 60 per mensem is now granted to officers below the rank of lieutenant-colonel but the concession which reads well means very little, for there are very few appointments ever made. Extra furlough is granted to officers who want to take up a special course of study, at the rate of one month of such furlough for each year's service up to 12 months in all. The pensions are increased, that for 20 years' service being raised from £1 per diem to £400 per annum, that for 17 years' service being £300 instead of £292; while Clause 39, which is as follows, is distinctly thought out for the officers' good :—

> [illegible]
> lieutenant-colonel who has b[illegible]
> if he attains the age of 55 [illegible]
> pension for 30 years service, [illegible]
> service; and in any special [illegible]
> good of the service that an [illegible]
> may be so continued, subje[illegible]
> Secretary of State for India in Council.

But the hardship experienced by the officer who enters the service when he is only a day over 25 years of age is to a large extent unredressed, for he forfeits almost to a certainty his chance of ever reaching a higher pension than £500 per annum. It is an absurdity to invite men into the service up to the age of 28 years and at the same time to inform them that the maximum pension is not open to them. As a rule, the men who enter the service after 25 years of age are those who have spent additional time in study in resident hospital posts or in junior teaching appointments in the schools, and such men ought to be encouraged in every way.

The blot in respect of the language examination still remains. No officer, however employed, can receive any staff allowance until he has passed the "lower standard" examination in Hindustani. The hardship of this lies in the impossibility which an officer on first joining the service may experience in obtaining tuition for an examination that is no longer an absolutely easy one. If his frequent moves do not break up his studies, he may be allocated to some remote station where he cannot obtain the services of an instructor; and in either case he is precluded for a long time from drawing his proper pay. A young staff corps officer posted to a native regiment receives full pay for one year pending his passing his examination in languages, and the same treatment should be extended to the young officer of the Indian Medical Service.

Turning from the military to the civil side of the service we find that the conditions of civil employment are practically unaltered in the new regulations, although three-fifths of the service are in civil employment. An improvement in the pay of the officers in civil employment may have been contemplated, increase and emolument on the military side of the service naturally leading to proportionate increase on the civil side, but the new regulations repeat the instructions that have been in force for years. A surgeon in the Indian Medical Service in civil employment has enormous responsibilities. He acts as sanitary and medical superintendent of the gaol and its hospital, is surgeon to the police, is responsible for the food of the prisoners and for the purchase of the raw materials which their labour is to turn out into marketable manufactures. He may have several outlying dispensaries which he is bound to inspect regularly and which may be four or five days' journey from headquarters, where he also has a dispensary attached to the urban hospital. For the arrangements of his official work and the necessary correspondence he is responsible absolutely. He is assisted only by natives and he has to make good any deficiency in his accounts. For all this he receives less than if he were in medical charge of a regiment, although he has applied successfully as a specially gifted man for civil employment. It is no wonder that there is difficulty in getting candidates to pass from the military side into civil employment, while it is certain that if the best work in the service is the worst paid that service needs reform.

---

[1] Chapters I., II., III., IV., V., VI., and VII., were published in THE LANCET of Feb. 18th (p. 447) and 25th (p. 517), March 4th (p. 593), 18th (p. 736), and 25th (p. 817), April 1st (p. 877) and 8th (p. 1017), 1905, respectively.

Again, the order that an officer of the Indian Medical Service should refer the question of the amount of his fees, when above a certain low limit, to the civil authority is highly vexatious. No similar proceeding is ordered in any other service in India or elsewhere, and the suggestion that without some such restriction exorbitant fees would be exacted is most unfortunate. This regulation, which has recently been modified but not in a way to remove its sting, points to an official belief that the native, unless protected by the Indian Government, would be exploited by the officers of the Indian Medical Service, a reflection that is felt by many men to be humiliating. It is tantamount to saying that because very large fees have occasionally been received by medical men in India other medical men unless prevented will take unscrupulous steps to obtain a like reward.

The pay of the Director-General of the Indian Medical Service has been increased, as has been said, but his rank remains unaltered. His rank should be increased from that of major-general to that of lieutenant-general, in accordance with the similar concession that has been made to the Director-General of the Army Medical Service, while he should by virtue of his office have a seat on the Viceregal Council and the surgeon-generals of the several provinces should similarly sit on the Councils of the Lieutenant Governors. If medical views could be placed directly before the rulers of the Indian Empire and if the reasons for medical suggestions could be personally explained to the heads of the legislative machinery not only would much needless friction be abolished but more efficacious work could be done.

Lastly, something should be done to increase the rates of temporary and permanent half-pay for those who break down in India and are really incapacitated. Many of the captains in the service are married and the sum of £127 15*s.*, the rate of permanent half-pay accorded to them, is very small. All of us know of cases where men have been so broken down by the Indian climate that they have been forced to retire on this pittance and in a condition where work in private practice in this country is not possible to them. The rates of half-pay are less than those offered to the officers of the Royal Army Medical Corps and they stand in need of revision.

The Government of India owes, perhaps, more to the Indian Medical Service than to any other department in the country. From the days long ago when an Indian surgeon obtained a grant of land for the old East India Company from the then reigning Mogul up to the present time its officers have laboured far and wide in our great dependency for the cause of the Crown. But their recognition has been scanty; and even now that reform has come it has not come in any complete or satisfactory way.

The Naval Medical Service.

Like the Army Medical Service the Naval Medical Service, after enjoying a respectable measure of popularity in the profession for some years, began about 1890 to lose in the eyes of the student the inducements necessary to make him seek a commission. There grew up a feeling in the medical schools that the career offered in the service could not possibly terminate in anything but mediocrity. It was true that the naval medical officer saw the world under splendid auspices; that he picked up, or might pick up, a knowledge of nations and languages denied to his civilian brother; that the work was often not hard and that the pay could not be described as bad, when the cost of living on shipboard is considered. All that was allowed, but when said there was nothing to add. The opportunities for the study of disease that presented themselves to the naval medical officer could not be used save under substantial disabilities. A surgeon in the navy had no opportunity given to him to prosecute scientific research and was obliged to purchase for himself any instruments that he might require. No encouragement, moreover, was offered to the young medical man who desired to investigate some of the numerous problems in tropical disease that lay unravelled beneath his hands. Time spent in such work probably would not win him the commendation of his seniors, while such commendation, if forthcoming, would be but a barren reward in a service where promotion was governed by seniority rather than selection. The service as a consequence was depleted by retirement, withdrawal, and resignation, and the candidates for admission became fewer. The absolute necessity for study-leave and for increased pay, having regard to the slow advance in rank, became obvious, and grievances in respect to the allotment of cabins and the limited boat privileges, which were of real if minor import, were used to reinforce the claim for reform.

Apart from other considerations the re-organisation of the Army Medical Service under the warrant of 1902 made it imperative on the Admiralty to draw up and to issue fresh regulations for the medical department of the Royal Navy. The new warrant appeared almost simultaneously and it was at once seen by those who were thinking of the Naval Medical Service as a career that innovations had been introduced of an advantageous character to the medical department. Comparison with previous regulations showed that a great deal could be done under the amended scheme to increase the efficiency of the Naval Medical Service and to improve it generally, while additional inducements could be held out to those who were thinking of becoming candidates for admission into the service. The framers of the new regulations set about their work in a sincere spirit, the objects aimed at were in the right direction, and the improvements introduced were of a necessary and wholesome kind.

The warrant does not go far enough in some directions and, as will be seen, leaves undealt with matters that are regarded as serious by the officers of the Naval Medical Service, but in the medical profession generally it should restore a waning confidence. It shows a desire to bring the service up to the higher standard demanded by the general progress of medicine. To a great extent the regulations for the Naval Medical Service are framed on the lines of those in the new warrant for the Army Medical Service. The entrance examination becomes of a more practical and clinical nature, better adapted to, and more befitting, candidates already qualified to practise their profession. The subjects are divided into compulsory and voluntary and the voluntary subjects are selected with a view to secure men with some knowledge of foreign languages and aptitude for natural science. Provision is reserved for the Admiralty to appoint at its discretion a limited number of candidates from medical schools in the United Kingdom and the colonies without any competitive entrance examination. Resident medical officers, house physicians, and house surgeons of large civil hospitals can be promoted to the rank of staff surgeon six months or a year earlier than their fellows, and by a later regulation of the Admiralty a successful candidate for a commission is allowed to serve as a hospital resident for a year after entering the service and to count the time for promotion. An officer can retire after four years' full pay service with a gratuity of £500 and serve in the reserve under conditions which certainly cannot be called onerous.

These changes are intended to insure that those most fully educated and least crammed will be selected for the service, if a sufficient number of candidates put in their appearance, and thus the principle of selection can be adopted at the very outset of the naval medical career. With the exception of a few specified appliances, a pocket case of instruments, a stethoscope, and three clinical thermometers, all surgical instruments are supposed to be provided at the public expense. A very important regulation is introduced in regard to courses of instruction, under which medical officers can have practical opportunities and facilities for keeping abreast with the progress of their profession and for studying special branches of it.

Every medical officer is now required to undergo a post graduate [illegible] skiagraphy.

All this spells great improvement, though in detail the warrant has not escaped criticism. It will be observed that the medical officers of the navy are required to undergo the course of post-graduate study at their own expense, although lodging allowance is paid to them, as it is to all other officers not provided with quarters on a ship. To produce separate certificates of efficient attendance upon classes in the five named subjects would cost in any London school about £35, which is a severe tax. The time, it is hoped, may be approaching when our naval medical officers will receive full subsidies from Government. That time will be when the Admiralty recognises that a medical officer in the navy does not exist only "to doctor people" but that he has functions of the highest importance to discharge in the prevention of disease.

As regards pay and allowances and charge pay all are somewhat improved. The application of the principle of promotion by selection instead of seniority is more fully recognised and encouragement is held out to professional merit. Better provision is made for cabins for naval medical officers. In short, the new regulations for the Medical Department of the Royal Navy are directed towards the reform of manifest abuses. The new warrant for the Army Medical Service offers points of comparison. The army officers have an opportunity of gaining from three to 18 months' earlier promotion on passing their promotion examination with distinction, but no such provision prevails in the navy. In the army allowances are better, the new regulations for full-pay sick leave are more generous, and charge pay is provided for officers of whatever rank in charge of beds according to numbers, whereas in the navy there is charge pay for inspector-generals only, a very limited number. In attempting to estimate the Naval Medical Service as a calling by comparing it with the Army Medical Service more attention should be paid to points in which the former has an advantage over the latter. Take, for example, the question of allowances. In the army officers have to maintain lodgings, board, and servant, while in the navy an officer has a furnished cabin, a servant, and a capital mess, for which he pays 2*s.* a day only, so that from a pecuniary point of view, if a man is careful, the navy is the better service. In the Naval Medical Service promotion is given for "distinguished service or conspicuous professional merit" and such promotions are maintained up to the full number allowed. Officers may get on the list of staff-surgeons—i.e., officially ranking with major—who have not more than four or five years' service as surgeons. Although all the officers in charge of small hospitals or marine infirmaries belonging to the navy do not get "charge pay" they get it as "hospital allowance." With regard to full-pay sick leave it is true that the army medical officer is better off, but all naval officers, and not only naval medical officers, suffer in the same way by comparison with the army officers. Under the new warrant a bid has been made for candidates of the best sort. A man can now fill the coveted junior posts at his hospital and count the time for promotion, he can retire in favourable circumstances if he finds that his bent is more towards civilian practice, and he has opportunities afforded him for scientific work. There is plenty of room for criticism but much progress has to be admitted.

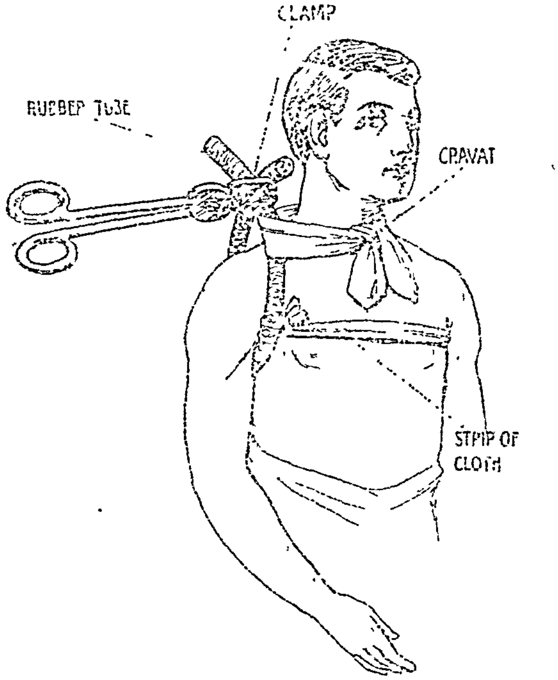
The various advantages and disadvantages of joining the three services counterbalance each other fairly, and it must be generally allowed that in each the position for the medical profession is a hopeful one. There are many matters that call for legitimate criticism, but in all three services the tendency is towards the recognition of scientific merit, while the recent concessions to professional opinion and common sense may be regarded as an earnest for further reform. I would summarise the position as follows. Whereas a few years ago the dean of a medical school who allowed his pupils to enter for commissions to any of the three services without warning them of possible disappointment defaulted in his duty, to-day if he recommended a promising young medical man not to compete for a commission he would take upon himself a great responsibility. In all three services there is increasing scope for the best sort of scientific medical men and although it is the duty of deans and teachers to be aware of the drawbacks to the services they should also be acquainted with the movement towards far better things.

(To be continued.)

THE CONSERVATIVE TREATMENT OF TUBERCULOUS ARTHRITIS.

Professor Bier has lately reported in the *Münchener Medicinische Wochenschrift* a number of remarkable successes in the treatment of acute and chronic osteomyelitis. As we have received inquiries from more than one correspondent as to what Professor Bier's technique is we publish the following account, which has been sent to us by our Swiss correspondent.

After studying the question of the conservative treatment of joints affected by tuberculous processes by means of passive hyperæmia, Professor Dr. A. Bier, who occupies the chair of clinical surgery at Bonn (Germany), gives the following description of his method in his treatise on Hyperæmia (Hyperaemie als Heilmittel). He employs constriction of the limb *above* the affected joint by means of a rubber (Martin) bandage applied over a gauze bandage which is to prevent excessive pressure. The rubber bandage must not be applied tightly enough to cause either pain or paræsthesia. If it causes discomfort it should be loosened at once; on the contrary, pain in the diseased joint should disappear during the application of the bandage. The subcutaneous veins swell and the skin assumes a bluish tint; in the case of the arm, the elbow and the palm of the hand only retain a rosy hue. The parts peripheral to the bandage should show an increased, never a decreased, temperature. This constriction can be applied over all joints except the hip-joint. In the case of the shoulder-joint the technique is not quite so simple. A necktie is loosely tied round the neck like a cravat (see illustration). A thick rubber tube is passed round the shoulder-joint as high as possible, one end being inside and the other outside the necktie. The ends of the rubber tube are firmly tied together, the knot being secured by a pair of artery forceps to prevent it slipping. Cotton-wool is used as a pad underneath the rubber tube to avoid undue local pressure. A bandage passed round the opposite axilla secures the tube more firmly and keeps it in position. In the case of tuberculous joints when only constriction of short duration is applied the peripheral portion of the limb is not bandaged. The surgeon himself should apply the constriction several times and in the case of patients wanting in intelligence even a good many times, but afterwards the patient or his friends can continue the simple treatment with due precautions. The constriction should *not* be allowed to remain on *more than one hour a day*. Thus Professor Bier has succeeded in avoiding some very disagreeable consequences which ensued when constriction was employed many hours consecutively. These complications were the formation of luxuriant granulations, of large or numerous small abscesses, or even the occurrence of acute inflammation. Very often cold abscesses appear during treatment, as the latter promotes the elimination of morbid material. The abscesses are best incised and treated antiseptically. Sometimes small pieces of necrosed bone have to be removed. The results are at times very striking, mostly gratifying, as the tuberculous process becomes extinct after a treatment varying from three to six months or longer. Professor Bier prefers the patients to move their diseased limbs as much as the pain will allow. If these methods fail he resorts to operative interference. The following cases speak well for the results. Case 1. The patient was a boy, eight years old, who had tuberculous arthritis of the knee-joint of two years' duration. There was subluxation of the tibia backwards with some flexion but little pain. He could not walk. Injections of iodoform and treatment with superheated air were tried without any benefit. Hyperæmia, induced by constriction from May 14th to June 27th, 1892, brought the process to a standstill. After ten years, the young man had a moveable knee-joint without any thickening; he can stand and walk all day and only limps a little after great exertion. Case 2. The patient, a young tailor, aged 17 years, had suffered from tuberculous disease in the small bones of the wrist for two years. There was a spindle-shaped swelling. The joint was almost immoveable owing to great pain and adhesions. The hand was useless. Constriction was applied from June till August, 1892. The young man is now well and is gaining a living as a groom. Case 3. The patient was a girl, aged 11 years, with a spindle-shaped swelling of the elbow joint, which was fixed at a right angle, the movements being very limited and painful. Constriction was employed daily for one hour from March 15th to June 26th, 1892. After ten years, the girl could use her arm for every kind of work, though after great exertion the joint feels weak. This conservative method of treatment is both simple and cheap and it can be employed for out-patients with little supervision after the first weeks. If other observers do not report as favourably about it their technique may be at fault.



The size of the clamp and the rubber tube has been exaggerated in the sketch.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

ELECTION OF PRESIDENT.

AN extraordinary Comitia was held on Monday, April 17th, Sir WILLIAM S. CHURCH, Bart., K.C.B., the President, being in the chair.

The PRESIDENT announced that the Gilbert-Blaine medals had been awarded to Staff-Surgeon Sidney Thomas Reid, H.M.S. *Vestal*, and to Surgeon Robert William Glennan Stewart, H.M.S. *Thames*. He also announced that the Bisset Hawkins medal had been awarded to Sir Patrick Manson.

The PRESIDENT delivered the usual annual address in the course of which he referred to the lives of eight Fellows who had died during the year—namely, Dr. Charles Kelly, Dr. T. Gilbart Smith, Sir Frederic Bateman, Dr. Angel Money, Dr. William Lee Dickinson, Dr. G. Vivian Poore, Dr. W. G. V. Lush, and Dr. Adam Bealey. The President referred to the Royal honours and distinctions which had been conferred on certain members of the medical profession and to the awards of medals, prizes, and scholarships connected with the College. He also mentioned the lectures which had been delivered, drawing especial attention to the Harveian oration and to the Fitz-Patrick and Oliver Sharpey lectures. He then reviewed some of the work accomplished by the College and the many important committees which had been appointed during the year, particularly that concerned with communications with various departments of State.

Sir HERMANN WEBER proposed a vote of thanks to Sir William Church for having acted as President during the past six years. He also thanked him for his address and requested that it might be printed and distributed to the Fellows.

Sir WILLIAM CHURCH returned thanks to the College and acceded to the request to have his address printed. He then vacated the chair.

The REGISTRAR (Dr. E. LIVEING) read the regulations which govern the election of President. The election was proceeded with. At the first ballot the result was as follows: Sir Richard Douglas Powell, 51 votes; Sir William H. Broadbent, 50; Dr. P. H. Pye-Smith, 27; Sir Thomas Barlow, 2; Sir John Williams, 1, Dr. W. H. Allchin, 1; Sir William Church, 1; Dr. F. W. Pavy, 1; and Dr. D. Ferrier, 1 A second ballot was then taken, with the result that Sir R. Douglas Powell was elected President, receiving 74 votes, while Sir William Broadbent received 59.

The charge was delivered by the SENIOR CENSOR (Dr. T. H. GREEN) and the PRESIDENT pledged his faith to the College

Sir R. DOUGLAS POWELL thanked the College for the honour that had been accorded to him in electing him as President.

Licences to practise physic were granted to Sydney Herbert Daukes, Cambridge and London Hospital; David Morgan

Jones, Glasgow and London Hospital; William Herbert Lowry, Toronto; Edgar Coningsby Myott, Manchester and Guy's Hospital; and Lewis Thomas, Dalhousie and the Middlesex Hospital.

The following communications were received:—1. From the secretary of the Royal College of Surgeons of England reporting certain proceedings of its Council on Feb. 9th. 2. From the secretary-general of the International Congress of Medicine to be held at Lisbon from April 19th to 26th, 1906, asking the College to send a delegate to represent it at the Congress. It was resolved to send a delegate who should be nominated by the President.

Dr. NORMAN MOORE proposed the following motion:—

> That in view of the constantly increasing mortality from plague in [illegible] Government on the subject.

This was seconded by Sir DYCE DUCKWORTH, supported by Dr. J. F. PAYNE, and carried. The nomination of the members of the committee was left in the hands of the President.

A communication was received from Dr. W. H. Dickinson resigning his office of curator of the museum and Dr. S. J. Sharkey was elected as his successor. A vote of thanks was accorded to Dr. Dickinson for his past services. The PRESIDENT then dissolved the Comitia.

MEDICINE AND THE LAW.

The Medical Man's Evidence in a Court of Law.

IN the learned paper entitled "Notes upon the Law of Evidence," read by Mr. Justice Walton at the recent meeting of the Medico-Legal Society, he thus summed up his practical advice to witnesses, medical and others: They must listen to the whole question propounded before venturing to reply; they must say exactly what they mean; they must not manifest a spirit of suspicion in the witness box; and above all they must not worry themselves with a fear of infringing technical rules of evidence. A suspicious demeanour will bias both judge and jurors unfavourably. The infraction of any rule of evidence will be keenly watched for by the opposing counsel—*c'est son métier*. Relevant evidence to be valid must be given in court, under oath and subject to rigid cross-examination. Hence, only original facts actually seen and heard are admitted and they must be evidenced solely by those who saw and heard them. A cardinal rule of wide application is that hearsay testimony must be rejected; thus Sir Thomas Stevenson was stopped from offering testimony as to the results of a chemical analysis performed by his assistant. It may be stated broadly that it is in the interest of public justice that the law imposes its limitations and exceptions to what are considered the general rules of logic and common sense. A judicial trial is unlike a scientific investigation for the juror is an untrained observer and a legal issue cannot be postponed indefinitely from time to time for further or more accurate inquiry. There are, however, a few apparent exceptions to the principle of the rejection of hearsay testimony but on investigation it will be found that most of these exceptions are more or less in the nature of original evidence. Many instances of these exceptions are specially pertinent to medical men who would be wise to record at once in black and white any statements which may have to be repeated by them in court. Hearsay testimony is commonly allowed in the coroner's court and this in spite of the accidental fact that the press, by publishing the facts elicited by the inquest jury, may prejudice public opinion. It is the medical adviser who often catches the last whisper of a victim conscious of impending dissolution as to the cause of the fatal event. Lastly, the evidence of a medical practitioner may be important when the legal doctrine of the admissibility of statements in the nature of *res gestæ* is applied. Words may be repeated as evidence where an exclamation forms part of th [illegible] stion, as Dr. Blake O. [illegible] rather of *when* than [illegible] The natural expression of a frightened man who has allowed himself no time to concoct a lie is an example; the cry of the newly born babe may be adduced in evidence of live-birth, although there may be *vox et præterea nihil*. The words may be uttered by an offender or by a victim, as in the case of an indecent assault or of a rape, in which cases a considerable interval of time has been allowed to elapse after the alleged act and before the statement was made. Sir Joseph Walton further gave as an exception where hearsay testimony was allowed statements made to a medical man by his patient describing symptoms—that is, what is felt and suffered; the admission of such testimony might also be justified upon the ground that it is [illegible] ntary information that the [illegible] at a correct diagnosis and to prosecute a line of treatment and as his diagnosis may be demanded in court the facts which led up to it should also be allowed. The learned judge strongly approved of medical assessors in place of medical experts as witnesses; it is well known that Sir Joseph Walton uses assessors frequently and he regrets that the powers given to common law courts to employ them, under the Judicature Acts, are so neglected. While admitting the benefit of assessors in civil courts, he considers that it will be impossible to extend the practice to criminal courts, for th [illegible] and therefore counsel [illegible] of the present law in [illegible]

Russian Estimat of the Value of Formalin in Cases of Poisoning.

The Medical Council of St Petersburg, having considered the representation of one of the medical committees respecting the methods adopted to preserve intestines intended to be examined for judicial purposes, has decided that in cases where spirit cannot be employed a 10 per cent. solution of formalin may be used. But considering that formalin combines intimately with several substances and thus renders a proper investigation impossible, it appears necessary that at the time the intestines are placed in the said solution, a part of the stomach, bowels, &c., should be hermetically sealed in a vessel or vessels without the addition of any preservative substance whatever. Respecting the action of formalin the council observes that such poisons as strychnine, veratrine, morphine, atropine, and phosphorus will remain in the organs for a very long time with a 10 per cent aqueous solution of formalin.

Anthrax an Accident under the Workmen's Compensation Act.

Instances have frequently occurred in which there has been considerable legal dispute as to whether the term "accident" used in the Workmen's Compensation Act covers certain matters which in ordinary conversation we should hardly class as accidents. Infection with anthrax has been one of these and the tendency of recent decisions has been to class this and similar dangerous conditions arising out of the workman's employment as "accidents." The House of Lords has now upheld these, the Lord Chancellor observing, in moving the rejection of the employers' appeal, that it did not appear to him that by calling the consequences of an accidental injury a disease the nature of the consequential results of the injury was affected. He gave as parallel instances infection with anthrax, erysipelas, or tetanus following slight accidental injuries perhaps not noticed at the time and not necessarily followed by these results. The question is one of legal rather than of medical importance but for the fact that at the hearing of claims of the kind referred to medical men are the most important witnesses called and that it is consequently useful for them to bear in mind when treating their patients that legal inquiry will follow in which their procedure, among other matters, will probably come under discussion.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8560 births and 4958 deaths were registered during the week ending April 15th. The annual rate of mortality in these towns, which had been 15·9, 15 7, and 15·7 per 1000 in the three preceding weeks, rose again to 16·6 per 1000 last week. In London the death rate was 16·1 per 1000, while it averaged 16·8 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 9 0 in Kings Norton, 9 3 in Handsworth (Staffs.) 9·6 in Leyton, 9·9 in Hornsey and in Burton-on-Trent, 10·3 in Walthamstow, and 10·6 in East Ham; the highest rates were

21·0 in Hanley, 21·2 in Middlesbrough, 21·3 in Manchester, 21·4 in Ipswich, 21·9 in Stockton-on-Tees, 23·8 in St. Helens, 26·3 in Tynemouth, 26·7 in Rhondda, and 31·1 in Merthyr Tydfil. The 4958 deaths in these towns last week included 553 which were referred to the principal infectious diseases, against 494, 483, and 430 in the three preceding weeks; of these 553 deaths, 231 resulted from measles, 148 from whooping-cough, 58 from diphtheria, 52 from scarlet fever, 42 from diarrhœa, 20 from "fever" (principally enteric), and two from small-pox. No death from any of these diseases was registered last week in Northampton, Great Yarmouth, Burton-on-Trent, Wolverhampton, Handsworth (Staffs.), Kings Norton, Wallasey, Bootle, Rochdale, Preston, Barrow-in-Furness, or Huddersfield; while they caused the highest death-rates in Southampton, West Bromwich, St. Helens, Sheffield, Stockton-on-Tees, Newport (Mon.), and Merthyr Tydfil. The greatest proportional mortality from measles occurred in Portsmouth, Southampton, West Bromwich, Coventry, Nottingham, Wigan, Sheffield, Middlesbrough, Stockton-on-Tees, Newport (Mon.), and Merthyr Tydfil; from scarlet fever in Blackburn and Merthyr Tydfil; from diphtheria in Ipswich and Tynemouth; from whooping-cough in Tottenham, West Ham, Hastings, Reading, and Hanley; and from diarrhœa in St. Helens. The mortality from "fever," showed no marked excess in any of the 76 towns. Two fatal cases of small-pox were registered in Southampton, but none in any other of the large towns. The number of small-pox patients remaining under treatment in the Metropolitan Asylums Hospitals, which had been 20, 20, and 21 on the three preceding Saturdays, had declined again to 15 on Saturday last, April 15th; no new cases were admitted during the week, the numbers having been three, two, and four in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of last week was 2133, against 2035, 2032, and 2086 at the end of the three preceding weeks; 290 new cases were admitted during the week, against 274, 254, and 292 in the three preceding weeks. The deaths referred to pneumonia and diseases of the respiratory system in London, which had been 304, 273, and 308 in the three preceding weeks, declined again to 304 last week, but were nine in excess of the number in the corresponding period of last year. The causes of 52, or 1·1 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in London, Portsmouth, Bristol, Nottingham, Salford, Bradford, Leeds, Newcastle-upon-Tyne, and in 42 other smaller towns; the largest proportions of uncertified deaths were registered in Leicester, Liverpool, St. Helens, Rochdale, Barrow-in-Furness, Rotherham, Sunderland, and South Shields.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 18·3, 16·9, and 16·6 per 1000 in the three preceding weeks, rose again to 18·0 per 1000 during the week ending April 15th, and was 1·4 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 14·0 in Paisley and 15·9 in Dundee to 24·4 in Perth and 24·5 in Greenock. The 603 deaths in these towns included 36 which were referred to whooping-cough, 17 to measles, nine to diarrhœa, six to diphtheria, and one to scarlet fever, but not any to small-pox or to "fever." In all, 69 deaths resulted from these principal infectious diseases last week, against 59, 43, and 73 in the three preceding weeks. These 69 deaths were equal to an annual rate of 2·1 per 1000, which was 0·3 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping-cough, which had been 33, 20, and 28 in the three preceding weeks, rose again last week to 36, of which 26 occurred in Glasgow, four in Edinburgh, and two in Greenock. The deaths from measles, which had been six, five, and 13 in the three preceding weeks, further rose to 17 last week, and included 11 in Glasgow, two in Edinburgh. and two in Aberdeen. The fatal cases of diarrhœa, which had been eight, eight, and 20 in the three preceding weeks, fell again last week to nine, of which three were registered in Glasgow, two in Dundee, and two in Aberdeen. The deaths from diphtheria, which had been five in each of the two preceding weeks, increased to six last week, and included two in Glasgow and two in Edinburgh. The deaths referred to diseases of the respiratory organs in these towns, which had been 133, 105, and 119 in the three preceding weeks, further rose last week to 121, but were 31 below the number in the corresponding period of last year. The causes of 18, or nearly 3 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 22·4, 24·9, and 25·5 per 1000 in the three preceding weeks, declined again to 21·6 per 1000 during the week ending April 15th. During the past four weeks the death-rate has averaged 23·6 per 1000, the rates during the same period being 15·6 in London and 16·4 in Edinburgh. The 157 deaths of persons belonging to Dublin registered during the week under notice were 28 below the number in the preceding week and included eight which were referred to the principal infectious diseases, against seven, eight, and five in the three preceding weeks; of these, four resulted from measles, two from whooping-cough, one from scarlet fever, and one from "fever," but not any from small-pox, diphtheria, or diarrhœa. These eight deaths were equal to an annual rate of 1·1 per 1000, the death-rates last week from the principal infectious diseases being 1·8 in London and 1·2 in Edinburgh. The fatal cases of measles, which had been four, four, and none in the preceding weeks, rose again last week to four. The 157 deaths in Dublin last week included 19 of children under one year of age and 47 of persons aged 60 years and upwards; the deaths both of infants and of elderly persons showed a considerable decline from the respective numbers recorded in the preceding week. One inquest case and two deaths from violence were registered; and 58, or more than a third, of the deaths occurred in public institutions. The causes of seven, or more than 4 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Staff Surgeon G. A. S. Bell to the *Victory*, to be lent to the *Brilliant*, temporary.

The following have been promoted Surgeons: C. H. Rock to the rank of Fleet Surgeon, with seniority of May, 1903; H. H. Gill to the rank of Fleet Surgeon, with seniority of November, 1903; and A. T. Wysard to the rank of Fleet Surgeon, with seniority of May, 1904.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel W. Baker, on reversion from India, is appointed to the Eastern Command for duty. Major C. J. Holmes (retired pay) assumes medical charge of the Station Hospital and troops at Warrington, vice Lieutenant-Colonel C. W. Thielé. Major R. H. Penton joins at Portsmouth. Major A. Hosie is posted to the Eastern Command. The following officers in India have been appointed to the command of the station hospitals named: Captain J. A. Hartigan, Cherat; Major H. A. Cummins, C.M.G., Baragali; Major J. J. Russell, Kuldana; Major C. Dalton, Gharial; Major W. G. Beyts, Solon; Captain T. F. Ritchie, Khairagali; Captain H. Rogers, Changlagali; Captain J. H. Robinson, Kelabagh; Lieutenant P. Davidson, D.S.O., Ghoradaka and Kharspur; Captain J. Powell, Thobba; Lieutenant H. G. S. Webb, Upper Topa; and Lieutenant C. A. J. A. Balck, Lower Topa.

Major William Boog Leishman, Professor of Pathology, Royal Army Medical College, to be Brevet Lieutenant-Colonel, in recognition of his services and the distinction attained by him in original investigation and research (dated April 15th, 1905).

VOLUNTEER MEDICAL CORPS.

Surgeon-Lieutenant-Colonel W. Mitchell Roocroft, V.D., is granted the honorary rank of Surgeon-Colonel (dated March 18th, 1905).

THE MEDICAL JOURNAL OF THE ITALIAN NAVY.

The *Annali di Medicina Navale* enters upon its eleventh year with a double number of 240 pages, of which nearly one half contains original contributions from naval medical officers, while the remainder consists of a periscope of cosmopolitan current medical literature. A nominal roll of the medical department of the Royal Italian Navy accompanies this number. It contains the names of 227 officers who rank as follows:—Major-General 1, Colonels 6, Lieutenant-Colonels 11, Majors 23, Captains 107, and Lieutenants 79. The names are also given of 67 medical officers belonging to the Reserve and of 13 apothecaries. Medical officers, it will be seen, are accorded military titles, but the same distinction is not conferred upon the *Farmacisti.*

Correspondence.

"Audi alteram partem."

DISAPPEARANCE OF AN APPARENTLY MALIGNANT TUMOUR OF THE THROAT.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of March 25th, p. 821, Mr. F. W. Joshua raises the following question: Can a malignant tumour—a well-marked cancer—disappear spontaneously? An answer to this question has already been given by Mr. D'Arcy Power in a paper read before the Harveian Society of London on March 2nd, 1899; both the paper and the discussion on it at the society were published immediately afterwards in THE LANCET, the former on March 4th (p. 583) and the latter on March 11th (p. 693). Mr. Power described a series of cases of disappearance of malignant tumours after laparotomy in apparently hopeless cases where owing to the extent of the damage, the size of the tumour, &c., no operation was performed. In some cases the diagnosis of malignant tumour was made microscopically from excised portions of the tumour.

In the issue of the *Correspondenzblatt für Schweizer Aerzte* for October, 1904, I published the following case under the title, "Disappearance of an Apparently Malignant Tumour of the Throat." The patient was a woman, aged 76 years, a very quiet, unassuming, reliable person, who consulted me on Jan. 5th, 1904, about a papillomatous tumour growing on the left side of the soft palate. She was not only old and infirm but she had degenerative changes in the arteries, a weak heart and had been suffering for many years from dyspepsia. The tumour slowly increased under simple treatment (gargles, mouth washes, tonics) and began to slough. A specialist for throat diseases who saw her in February confirmed my diagnosis of cancer. The patient declined the operative interference proposed by her two medical attendants. By March the tumour was of about the size of a small egg, had pushed the uvula over to the right side, and occluded the pharynx to such an extent that the patient was reduced to fluid nourishment. Codeine and morphine had to be given every night to alleviate the agonising pain which she suffered heroically without complaint. Thus a few hours' rest were insured. In March she insisted on operative interference. A surgeon who was called in considered the case past operation and there was swelling of the submaxillary glands on the left side. In order to insure proper feeding, per rectum if necessary, the patient went to a private hospital and remained a month under the charge and daily supervision of two surgeons. The case being pronounced hopeless she returned home on June 1st, 1904, to arrange her affairs. On June 2nd she suddenly felt better, had less obstruction in her throat, had the first painless night for four months, and has had no more pain since. On June 4th her husband and a hospital nurse discovered that the tumour had disappeared. The specialist who had seen her in January saw her again in July and confirmed the fact, so did I, and the hospital [illegible] er I [illegible] the [illegible] r is [illegible] ner [illegible] ood again, gets about as usual, and has regained her former state of health. She attributed her case of healing to a direct answer to personal prayer.

I am, Sirs, yours faithfully,

THEODORE ZANGGER, M.D.

Zürich, April 4th, 1905.

PUERPERAL SEPSIS AND THE CURETTE.

To the Editors of THE LANCET.

SIRS,—In the second portion of the paper by Mr. A. G. R. Foulerton and Dr. Victor Bonney on Puerperal Infections, published in THE LANCET of April 8th, p. 915, and April 15th, p. 992, there is a point which calls for some remark. After describing much valuable bacteriological work on the subject, they briefly discuss the *treatment* of the conditions and condemn curettage in the following sentence:—

> In the case of either a streptococcic or pneumococcic infection of the uterus, with or without secondary infection by other bacteria, this procedure would seem on the one hand to be incapable of doing any good, and on the other hand might be productive of most serious result by infecting the hitherto intact deeper tissues of the uterine wall.

This is misleading, as it suggests that those who advocate the active operative treatment of puerperal sepsis rely on the curette alone. Were this so, these strictures would be perhaps justified, though even then this condemnation seems to rest rather on bacteriological probabilities than on clinical experience.

But the essential point is that the curettage shall be followed by thorough disinfection of the raw surface, otherwise dissemination of infective matter might easily occur. I have myself had the best results from thorough removal of the endometrium with a sharp, light instrument (as distinguished from stirring up the surface with a heavy blunt one), followed by thorough rubbing with undiluted izal.

I am, Sirs, yours faithfully,

A. KNYVETT GORDON,

Medical Superintendent, Monsall Hospital; Lecturer on Infectious Diseases in the University of Manchester.

Manchester, April 15th, 1905.

THE MEDICAL INSPECTION OF SCHOOLS.

To the Editors of THE LANCET.

SIRS,—Certain developments are taking place in connexion with the medical inspection of elementary schools which the profession would do well to follow closely, for they affect at once the health of the community and the progress of medicine. Sir William Anson states that every local educational authority has power to appoint medical inspectors to every elementary school and the Government has recently appointed a committee to inquire into what is being done in this respect.

Already medical officers of health take much interest in the elementary schools in their districts. Under the Education Code the sanitary authority of a district, or any two members thereof acting on the advice of the medical officer of health, can require either the closure of the school or the exclusion of certain children. These powers are from time to time exercised. Further, one medical officer of health analysed the air in one school and as a result made certain recommendations as to ventilation, and we have another reporting that epidemics are mainly kept up by attendance at school and complaining that head teachers are not sufficiently careful to exclude children slightly ill or those coming from infected houses. Besides this, one educational authority has decided to appoint a medical officer at a commencing salary of £400 a year. Another has appointed the medical officer of health to be medical officer to itself. A third has evidently appointed a medical officer, for it has decided that he should meet parents at a certain school twice a week and at outlying schools once a week. Lastly, we have a conference on school hygiene recommending that every educational authority should have a medical adviser.

Now, to advise a committee is one thing, to inspect children a second, and to treat those found to be ill is a third. As to the first, the best adviser on questions of lighting and the prevention of myopia would be an ophthalmic surgeon, but he would not, if he could, advise on the prevention of [illegible] matters of ventilation and drainage; [illegible] ppoint a consultative b[illegible] health might be a me[illegible], [illegible] to others his duties and powers as to the compulsory closure of schools. With respect to the medical inspection of schools it would seem best to appoint a separate practitioner to each school, who should attend daily at a fixed time and at other times when necessary. A medical officer to an authority with thousands of children in scores of schools could only visit each school occasionally, even though he gave the whole of his time to his duties. What he would probably do is to try to train the schoolmasters and attendance officers to diagnose infectious cases and keep medical records, but these are essentially medical duties and could only be done by schoolmasters at the expense of their proper work—i.e., teaching. Two objections can be made to this proposal: first, that the medical school inspectors being allowed to practise would be brought into unequal competition with their professional brethren, but divisional surgeons of police practise and no one proposes they should be debarred from so doing; secondly, it might be said that in the poorer parts of large towns the practitioners have been brought so low by the competition of hospitals and other causes that they would be unfit for these duties; even if this be admitted, which it is not, all that is necessary would be to require the holder of the post to reside within a mile of his school and to be on the telephone.

Many educationists will not be content with medical inspection but will want to go on to treat the children at the expense of the rates; it is to be feared, too, that some of them will care little whether the law authorises this or not but proceed to levy the higher rate, leaving anyone to stop them who can; if they do this they will find they have to appoint a regular medical staff and to maintain a children's hospital. The medical profession can, of course, take no part in proceedings of doubtful legality. Sir William Anson says there is grave doubt as to whether the Education Board has power to compel local authorities to appoint medical inspectors; there may be grave doubts about other matters; how far, for instance, medical inspection may be carried and by what action, if any, it may be followed. The Education Acts say the committees have power to appoint necessary officers and to assign to them their duties; everything then depends on what is considered necessary. The Education Code knows nothing of medical inspectors of schools; it has a schedule on pensions for teachers but nothing about pensions for medical officers; indeed, the only medical officer the code seems ever to have heard of is the medical officer of health.

But another question arises, What will be the effect of all this officialism on the character of the profession and the progress of medicine? It is stated that from some cause the scientific output of existing State hospitals is disproportionate to the opportunities enjoyed; it is noteworthy, too, that architects are complaining greatly of the effects of municipalisation on their art. "It does not produce economic work; it cannot produce artistic work, and it is subversive of the interests of the individual from whom the new thing and the original thing is invariably derived."

I am, Sirs, yours faithfully,

April 14th, 1905. J. S.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The Housing Question.

THE housing committee's scheme for dealing with the Bordesley Green site was presented to the council on April 4th. It was, however, received with so much opposition that it was withdrawn. There were two principal lines of objection. One was that the plans were unsatisfactory—the rooms were too small and the sanitary arrangements were defective; the other was that the terms of the contractor who covenanted to build on the site were not financially good and emphasis was laid on the fact that no guarantee was given that the rents would remain fixed. The supporters of the scheme urged that the medical officer of health had approved the plans, and that no guarantee could be given that the rents would not be raised unless the corporation guaranteed that the rates would not be raised. As regards the financial aspect they agreed that no doubt more could be obtained for the land if they allowed better houses to be built but that the land was purchased for the provision of cheap healthy houses and not as a land speculation. The feeling of the majority in the council seemed to be that if they waited a little longer until the roads—in process of making—were completed and threw the site open to competition better houses and a better price might both be obtained. On withdrawing the scheme the chairman said he did so on the understanding that the matter should be brought up again on a further report as soon as possible. Closing orders in respect of a considerable number of houses have been made during the last few days.

Reports of Charities.

From the annual report of the Birmingham Lying-in Charity it is seen that, like the other local charitable institutions, it stands in urgent need of increased subscriptions. The medical portion of the report was most satisfactory, for although no less than 1199 children were born in the cases attended during the year there was no maternal mortality. Land has been purchased for the erection of a central home in connexion with the charity and £2000 have been subscribed towards the £6000 required for its completion. So unsatisfactory is the financial position of the Birmingham Homœopathic Hospital as disclosed in the annual report that the curtailment of the in-patient department is regarded as inevitable.

Care of Epileptics and Feeble-minded.

The Local Government Board has at last approved the scheme under which the Birmingham, Aston, and King's Norton boards of guardians are jointly responsible for the poor epileptics and feeble-minded persons in their districts. The new body, brought into existence by the Government Order, is the first of its kind in the country and is known as the Birmingham, Aston, and King's Norton Poor-law Establishment Committee. A building for the accommodation of 210 inmates is about to be erected, of which number Birmingham will contribute 110 and Aston and King's Norton 50 each. The expenditure will be divided in accordance with this proportion. In addition to being properly attended instruction will be given to the inmates in order that they may be as comfortable and at the same time as useful as possible. At the last meeting of the Smethwick education committee a letter was read from the Board of Education sanctioning the proposal to erect a special school for defective and crippled children.

Birmingham and Tuberculosis.

The report of the health committee for the past year was presented at the last meeting of the city council. From it I gather that tuberculosis was accountable for no less than 1071 deaths In order to lower if possible the high death-rate from this cause a system of voluntary notification has been instituted and a special inspector has been lately appointed to visit all houses in which death has occurred from this disease and to see that disinfection is thoroughly carried out. An amendment was moved and seconded that the health committee should take into consideration the provision of sanatoriums for the reception of tuberculous patients and this was finally adopted as a rider to the report, although the chairman of the health committee craved time in order to see the effect of the measures which it has just lately adopted.

The Midwives Act.

Under the Midwives Act of 1902, which has just come into operation, it is expected that the total number of registered midwives in the city will exceed 200.

Health of the City and District.

At the close of last week there were three patients in the isolation hospital suffering from small-pox, as compared with four at the close of the previous week. The annual reports of the medical officers of health of West Bromwich and Erdington have just been issued. The latter place, which is one of Birmingham's healthiest suburbs, had a death-rate for the year of 10·8 per 1000. West Bromwich, which is situated in a less salubrious district, had a death-rate of 15·9 per 1000. Both death-rates were well below the average for the last ten years.

April 17th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Liverpool Health Students' Association: Have Sanatoriums Proved Unsuccessful?

UNDER the auspices of the Liverpool Health Students' Association an interesting address was delivered by Dr. J. E. Nevins, physician to the Liverpool Workhouse Hospital, on the subject of the Prevention of Consumption, with special reference to Sanatoria. Dr. Nevins quoted various opinions, including that of Professor Rudolf Virchow, director of the Pathological Institute, Berlin, who had remarked: "It is therefore to be hoped that the public will recognise that the study of the cause and prevention of tuberculosis is a branch which is more likely to be of ultimate benefit to the community than the establishment of open air sanatoria ' Again Professor Maragliano said at the Madrid congress that "sanatoria would never diminish the number of cases of tuberculosis they must only be looked on as quarantine hospitals which were useless without general hygienic measures The sanatorium movement in England might be said to date from Dec 20th, 1898 when the King then the Prince of Wales presided at the meeting at *Marlborough House at which Sir William H Broadbent* said that sanatoriums "aim not only at prevention but cure They had also the statements of Mr T B Sellors of Balham who said of the consumptive artisan ' Here we have a man on whom others depend bound to die in a year or two if not treated by the open air system and that is *impossible* while Dr G A Heron, senior physician to the City of London Hospital for Diseases of the Chest said "Treatment as a hospital out patient was a farce, a mockery, a great waste of money, and a public scandal Was out patient treatment a fraud and a scandal? asked Dr Nevins Before sanatoriums were introduced the death rate of phthisis had fallen in 50 years by 50 per cent and it did not appear from statistics that before the days of sanatoriums people were bound to die in a year or two There were three essentials in the sanatorium treatment—constant fresh air, abundant feeding and regulated rest and exercise There was nothing new here Sanatorium treatment really meant putting patients in ideal conditions of life and there was no reason why they should think that fresh air was going to work miracles any more than in years past *What had been the results?* To speak broadly, they had heard that the sanatorium at the beginning was held to be for cure In the early days the reports issued stated that so many patients were cured , later the term used in the reports was "disease arrested and a year or two later a new term was used "disease *apparently arrested* *The speeches* made at the annual meeting of the National Association for the Prevention of Consumption seemed to be disappointing In fact they admitted that sanatoriums had not been a success up to the present The speakers, however did not say that the sanatoriums were a failure but that they had became so owing to the people sent there by medical men The results of the present day treatment must be taken in the broadest sense, because it was almost impossible to compare figures relating to sanatorium treatment inasmuch as they differed in the class of patients treated The figures *he was about to* quote were only put forward just as straws showing the direction of the current In five English sanatoriums one had 23 per cent of the patients dead in less than four years another had 25 per cent , another 30 per cent , another 32 per cent , and another 38 per cent , in the aggregate of 477 *patients* 128 *died in four years or less* giving a percentage of deaths of 26 7 In Germany the results were much the same With regard to one hospital where hopeless cases were excluded from the percentage of deaths the results showed that 23 per cent of the patients died within four years One very important point to be remembered was that in the early stages—and those were the cases desired by

[illegible] cured itself where the [illegible] er So far as the Heswall [illegible] connected was concerned the percentage of deaths for two years was 23 6 With reference to *pre s*natorium results Dr C T Williams gave details of the treatment of 1000 patients Of those only 48 died in four years giving a percentage of 4 8 but those were cases in the highest class of society Dr J F Pollock physician to the Brompton Hospital had analysed his cases and of 3566 hospital *out patients whom he was able to* trace only 129 had died in two and a half years giving a percentage of 3 5 Dr Hammer of Heidelberg gave statistics which showed that the figures in reference to out patients were considerably better than those for sanatoriums He did not go so far as to say that the sanatorium was a failure although he had his own opinion on that point but he wished to impress on his hearers that so far it had not proved itself a success having regard to the expense He had picked the most suitable cases from the Liverpool Parish Infirmary but they could not in parish life provide the early cases In fact, *in parish life* the early cases were not often seen and those coming under observation were not always willing to be removed to the sanatorium Dr Nevins summed up his remarks by saying that the sanatorium had done good work in teaching the gospel of fresh air but as a curative agent it seemed to him that it had not proved itself a success

The Mitchell Banks Testimonial

It is proposed to close the fund for the town's memorial to the late Sir William M Banks on April 30th The Lord Mayor has appealed for further donations

The Liverpool Hospital for Consumption

The annual meeting of the supporters of the Liverpool Hospital for Consumption and Diseases of the Chest, including that of the sanatorium at Kingswood Delamere Forest was held at the town hall, the Lord Mayor presiding The Lord Mayor, in moving the adoption *of the report regretted that the institution should be* in such an unsatisfactory financial position The past year had ended with debit balances in maintenance and capital accounts of respectively £560 and £1542 The debit balance in capital account resulted from payments to account of the new hospital in Mount Pleasant the deficit in respect of which and the extension undertaken in connexion with the out patient department was estimated at £5000 The new hospital was opened for the admission of patients on Jan 1st The Lord Mayor made an urgent appeal to the committee and all present to advocate wherever possible the value of fresh air The number of patients treated in the out patient department last year was 1904 At *the Kingswood Sanatorium at Delamere Forest* 175 patients were treated last year The results, as in previous years were satisfactory 71 1 per cent had left in good health not cured in the popular meaning of the term but with the disease either quite or very greatly *arrested and their prospects* of life and wage earning assured or greatly improved The hospital recently suffered a heavy loss in the death of Lady Willox who in conjunction with Mr W P Hartley built the sanatorium at Delamere Forest and the annexe to the hospital which has recently been rebuilt in Mount Pleasant Liverpool

April 18th

WALES AND WESTERN COUNTIES NOTES

(From our own Correspondents)

Sanitary Administration in the Wrexham Rural District

For some time after the passing of the Public Health Act 1875 which made it incumbent upon sanitary authorities to appoint medical officers of health it was the custom to elect to that office the Poor law medical officers with the result that in many districts there were several medical officers of health acting for one authority The Local Government Board has for a long time tried to remedy this unsatisfactory condition but in Wales there still remain eight districts with two *medical officers of health, two with* three and one with no less than four The rural district of Wrexham which at the last census had a population of 55 198 and an area of 58 932 acres is one of the districts with two officers In 1903 one of them died and the Local Government Board refused to sanction a continuance of the arrangement until a report upon the sanitary administration of the district had been made by one of its inspectors That report which has been written by Dr L W Darra Mair has now been issued It contains the very serious charge against the district council of having failed in its duty as a health authority as shown by the inadequate methods of administration and the many nuisances and unwholesome conditions directly traceable to those methods Dr Mair advises frequent inspection of the district the provision in populous places of drainage schemes the periodical *inspection* of water supplies and the provision of a small pox hospital He suggests also the appointment of one medical officer of health for the rural [illegible] for the borough of Wrexham and that such a

population is now about [illegible]

Porthcawl Rest

The only convalescent home in South Wales is the "Rest at Porthcawl on the Glamorganshire coast The annual report of the institution which was presented to the meeting of subscribers on April 12th is a record of very successful management and of the accomplishment of much good work

Altogether 1095 patients were admitted during the year and the expenditure amounted to £1815. There was a balance on the year's working of £456, but there is still a debt of £1376 to defray the cost of extensions which were made a few years ago. The home is usually closed during the winter months but during the past winter it was kept open for the reception of children from the Cardiff Infirmary and the experiment was sufficiently successful to warrant a repetition next winter when children will also be sent from the Newport Hospital and a few adults will be admitted from these institutions.

Cardiff Infirmary.

Dr. Thomas Wallace has been appointed honorary consulting surgeon to the Cardiff Infirmary upon the expiration of his term of office as honorary surgeon. Dr. Wallace has been connected with the infirmary for nearly 27 years.

Extension of the Borough of Cardiff.

The corporation of Cardiff is again considering the question of the extension of the borough boundaries. The area of the borough is at present 6373 acres, or about three times the size it was at the middle of the nineteenth century. On the Llandaff side and on the Roath side of the town a large population is gathered outside the borough and difficulties in connexion with sewerage and other matters have arisen which can be most successfully overcome by including the districts in question in the borough.

Brixham Health Report.

Mr. G. Blacker Elliott, the medical officer of health of the Brixham urban district, reports a birth-rate in the town during 1904 of 26·6 per 1000 and a death-rate of 14·6 per 1000. The zymotic death-rate was 2·2 per 1000. Mr. Elliott very properly urges the district council to provide an isolation hospital and a steam disinfector, with neither of which can a popular watering-place afford to dispense.

Conference on Vagrancy at Hereford.

At a conference of members of the Poor-law unions in the county of Hereford, held on April 11th, a decision was come to which should have the effect of discovering among the occupants of the tramp wards the men who are desirous of working if work can be found for them. Notice is to be given to the employers of labour in the unions concerned that upon application by them the workhouse master will send them when possible a man who may appear suitable for the work required of him. It was also decided by the conference, which was presided over by Sir John Cotterill, the lord lieutenant of the county, that each union should adopt uniform treatment in respect to those who applied for admission to the tramp wards. The necessity for taking some steps in the matter is emphasised by the fact that in the Hereford union, which has a population of 34,000, or more than one-third that of the whole county, 8633 tramps came to the workhouse during the past year, compared with 3385 in 1896, although the population of the union has not appreciably increased within the two periods.

The Administration of the Midwives Act in Herefordshire.

The Herefordshire county council has delegated its powers under the Midwives Act to a committee consisting of five members of the county council, Dr. Paul M. Chapman, Mr. Edgar F. Morris, and two ladies, one of whom is the matron of the Herefordshire General Hospital. The committee has adopted the unusual course of recommending the appointment of a person—presumably a woman—who shall act in the dual capacity of a supervisor of midwives in the county and superintendent of the nurses employed by the county nursing association. There is no county medical officer of health in Herefordshire.

Hereford County Asylum.

The number of patients in the Hereford County and City Asylum is reported to be 528, which number includes 50 from the borough of Cardiff. The charge for the maintenance of pauper patients chargeable to unions within the county has been reduced to 8*s.* 9*d.* per week per patient. The salary of the medical superintendent, Mr. C. S. Morrison, has been increased from £500 to £600 per annum.

Taunton Isolation Hospital.

At the meeting of the Taunton town council held on April 11th the isolation hospital committee reported that it had decided to make a charge to patients or parents of patients who were admitted into the hospital and who might be considered in a position to pay for treatment. The amount claimed would be at the rate of one guinea per week for an adult and half a guinea for a child. A considerable discussion arose over the report, the opinion being expressed that it was unwise to make any charge to patients, as in other towns people were encouraged to send cases of infectious diseases to the isolation hospitals and in other boroughs such fees had been abolished. Eventually it was decided to refer the matter to the committee.

April 17th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Candidature of Dr. Leonard Kidd as a Direct Representative.

AT a meeting of the Ulster Medical Society held on April 13th, a letter having been read from Dr. Leonard Kidd with reference to the Direct Representation for Ireland on the General Medical Council, it was decided, after a long discussion, to take no action at present in the matter. The question will come up again for discussion as a number of members of the society have signed a requisition for a special meeting to discuss the whole question of the representation of Ireland on the General Medical Council.

The Foreshore Nuisance on Belfast Lough.

At a meeting of the Castlereagh district council, held on April 14th, a letter was read from the Local Government Board stating that it had decided to make a provisional order forming a united district for the purpose of abating the nuisance on Belfast Lough of which complaint had been so bitterly made. A joint board, consisting of the corporation of Belfast, the Castlereagh rural district council, and the Holywood urban district council, is to be constituted for the united district and the expenses incurred in purifying the foreshore are to be defrayed by these bodies in the proportion of Belfast 85 per cent. and Castlereagh and Holywood each 7½ per cent.

The Drink Bill in Belfast.

From the figures published in Dr. Dawson Burns's annual report for last year it would appear that in Belfast, with an estimated population of 358,693, the expenditure on drink was in 1904 £1,126,893, a sum almost equalling its valuation. This sum is only £30,000 short of the total amount spent in the whole of Ireland on poor relief and medical charities and £47,000 less than the entire sum spent on primary education. This amount would pay the whole of the sum spent by the public health committee and leave a balance to discharge the liability in respect of the free libraries and technical education. Dublin spent in drink in 1904 £1,190,897.

Down District Asylum.

Mr. M. J. Nolan, resident medical superintendent of Down District Asylum, was on April 15th, in recognition of his admirable administrative capacity and of his services in promoting in every department the improvement and reorganisation of the institution, made the recipient of a congratulatory address and gold watch, while his wife was presented with a silver salver. Lord de Ros, K.P., K.C.V.O. (chairman of the asylum board of management), who presided, bore his own testimony to the improvement which had taken place in every department of the institution under Mr. Nolan's régime, while the Right Hon. Thomas Andrews, D.L. (chairman of the Down county council), laid stress on the fact that in connexion with all appointments Mr. Nolan excluded all political and sectarian considerations and invariably recommended the best person for the position.

April 17th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Amendments to the Workmen's Compensation Act.

THE *Journal Officiel* of April 2nd has just published various clauses amending the law of 1898 which deals with accidents to workmen. The following are the principal clauses affecting the medical profession. The employer is liable for all medical fees, for the cost of drugs and appliances, and for the funeral expenses, but these last are not to exceed 100 francs. The injured workman has the right to choose his medical man and his druggist but in this case the employer is only liable for medical fees and for the cost of drugs, &c., up to an amount fixed by the *juge de paix* of the canton in which the accident took place. This amount is to be settled by a tariff issued by the Minister of Commerce in accordance with the report of a special committee comprising representatives of both medical men and of druggists. In every case the employer alone is liable for the hospital expenses, which, however, all told must not exceed 4 francs per diem in Paris and 3 francs 50 centimes everywhere else. Medical men, druggists, and hospital authorities can sue the employer directly. While the injured workman is being treated the employer can nominate to the *juge de paix* a medical man who shall examine into the condition of the sufferer, and this nomination, duly visé'd by the *juge de paix*, shall give to the said medical man a weekly right of entry to the injured man in the presence of his own medical attendant, who shall be notified two days previously by registered letter. If the injured man shall raise any objections to this visit the payment of the daily indemnity shall be suspended by order of the *juge de paix* who shall notify (*convoquera*) the injured man by registered letter. If the medical man shall certify that the injured man is fit to go back to work and the patient shall deny this the employer may, in a case of temporary incapacity, demand from the *juge de paix* an expert medical inquiry to be held within five days' time.

The Action of the X Rays upon Non-suppurating Tuberculous Glands.

At the meeting of the Academy of Sciences held on March 27th M. Bouchard read for M. Bergonié a report in which the latter stated that some six months ago he had treated four patients who were suffering from non-suppurating tuberculous glands by the x rays. From the results obtained he had come to the following conclusions. In cases of multiple tuberculous glands the action of the x rays is markedly good. All the glands treated become smaller but they rarely disappear altogether. Glands in the neighbourhood of those affected, which are not treated and are protected from the influence of the rays, are in no way altered. The most efficacious radiations appear to be those which, either owing to their amount or their quality, produce a marked inflammation of the skin. Finally, the rapid decrease in the size of the glands does not, according to the observations made, affect the general health of the patients.

The Local Action of Antidiphtheritic Serum.

At a recent meeting of the Hospitals Medical Society M. Dopter mentioned that he had employed Martin's serum (*serum antidiphtérique antimicrobien*) in the form of pastilles, with a view to hasten the disappearance of the bacillus of Löffler from the throats of diphtheritic patients. M. Dopter had found that under the local action of the serum the bacilli disappeared in, at the most, five days, at least exceptions to this were very rare and relapses hardly ever occurred. The patients were given 12 pastilles per diem to suck, one to be taken every hour, and any gargling or washing out the mouth which could dilute the serum was forbidden. For bacilli growing in the nasal fossæ the serum was dried and used in the form of coarse snuff (*prises*), but results were less satisfactory than as regards the throat, where the pastilles appeared to prevent the onset of paralysis of the soft palate. By their use the duration of the period of isolation was shortened. M. Sicard, who spoke next, agreed with M. Dopter from his own experience. M. Lermoyez argued that the failure of the serum in the nasal fossæ was due to a faulty method of application. The coarse snuff could only act upon the very narrow passage taken by the inspired current of air. It would have been better to powder the dried serum very finely, for used in this manner it could be deposited over a larger surface than when used in the form of coarse snuff.

The Part played by Spray in the Dissemination of Infectious Diseases.

M. Busquet, [illegible] part which the spray [illegible] the transmission of [illegible] d at least for 50 metres and it also is carried high into the air so that it will fill with mist houses which are close to the water's edge. M. Busquet ascertained that on the sea front of Bab-el-Oued, near Algiers, at which place numerous sewers discharge, given a strong wind with thick spray, the usual number of germs in the air is trebled. With a gale blowing the proportion of germs is increased in a still higher ratio and virulent bacilli coli have been found. These researches show the necessity for the protection of shores from pollution by sewage.

The Emile Zola Foundation.

Madame Emile Zola has just made over to the Assistance Publique her property of Medan, which, under the name of the Emile Zola Foundation, will be carried on as a convalescent home for members of the female staff of the Assistance. Madame Zola reserves to herself the island and the chalet thereon. M. Mesureur, the director of the Assistance Publique, has intimated that he will do all in his power to get the superior council of the Assistance and the municipal council to accept the gift. He suggests that the public should be allowed to visit the house. It is expected that the municipal council will at an early date signify its acceptance of the gift.

April 17th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

The Number of Medical Students in Austria.

THE following figures are given in the half-yearly report of the Royal and Imperial Ministry for Education, under the supervision of which the universities, as public institutions, are placed. According to this report there were in the winter half-year 1904-05 at the University of Vienna 1490 male and 37 female matriculated students of medicine; in Innsbruck, 160 (males only); in Graz, which is the second German university, 300 males and five females; in Prague, 210 males and seven females; in Lemberg, 98 males and 10 females; in Cracow, 126 males and 36 females; and the Czech University in Prague had 386 male and 15 female students, making a total of 2770 males and 110 females, or a falling off by 7 per cent. when compared with the figures for the last half year 1904.

A New Institution for the Treatment of Lupus by Finsen's Method.

By the munificence of members of the Royal and Imperial family the nucleus of a fund has been formed for the erection of a special building for the benefit of sufferers from lupus vulgaris. Other gifts and donations having been added to that sum Professor Lang, the director of the dermatological clinic at the General Hospital, took the matter in hand and now a two-storeyed house has been opened with all apparatus necessary for the treatment. X ray work and operations can be performed in the house, besides the special Finsen treatment for which four arc lamps are available. The fees charged from those who are not entirely destitute of means amount to about 1*s.* 6*d.* per hour of treatment under light, whilst operations are free. 15 beds are also at the disposal of the director of the institution. It is worth while mentioning that several English physicians have been, or are, working there under the direct supervision of Professor Lang who is regarded as an authority on matters concerning the treatment of lupus.

Small-pox.

A case of small-pox has been notified to the sanitary authorities of Vienna. This once dreaded disease has been so extremely rare since 1870, when compulsory vaccination was introduced into the Austrian empire, that amongst the younger generation of medical men there is hardly anyone who has had the opportunity of seeing it. Only officers of the Army Medical Corps now and then see a case in the southern provinces, where the unintelligent population omit to have the children vaccinated. The present case was imported from France. Stringent prophylactic measures were, of course, adopted at once and the result was that there has been no extension of the disease. The man died after seven days' illness from degeneratio cordis. The effect of vaccination is well shown in the returns of the Registrar-General. In the whole empire there occurred during the five years 1899-1904 not more than 92 cases, mostly imported from abroad, with 41 fatal results, whilst during the similar period 1865-70 there were 5020 cases with a mortality of 22 per cent. It must be remembered that epidemics were not rare then.

The Treatment of Tuberculosis Laryngis by Sunlight.

In a paper read before the Medical Society of Vienna, Dr. Sorejo, director of the open-air sanatorium Alland, which is the largest institution of its kind in Austria, described his method of treating tuberculosis laryngis. The patient, sitting in front of a large ordinary mirror which reflects the sun's rays into his or her mouth, inserts a laryngoscopic mirror in the usual way into the mouth until the glottis becomes visible in the large mirror. Then the rays are sure to fall on the vocal cords. After some practice the patients are able to spend from 40 to 60 minutes in this way, changing their position according to that of the sun. The results, which were demonstrated on 14 patients, were so remarkable as to induce several eminent physicians to give the method a trial in their clinics. It is absolutely necessary to employ parallel rays, which seem to have beneficial chemical effects on granulations. Thus ulcers have disappeared in three cases, tuberculous infiltrations of the epiglottis and vocal cords have subsided in five cases, and a general improvement has followed in all cases. The experiments are now conducted in several hospitals. The only drawback is the uncertainty of sunshine in winter time.

Double Wound of the Axillary Artery.

Dr. Weiss showed at the last meeting of the Clinical Society a man who had been stabbed in the left shoulder. After a copious hæmorrhage he was taken to a hospital where he was attended to. A prominence under the left deltoid muscle was attributed to a hæmatoma, and the diagnosis of a wound of the arteria circumflexa humeri having been made treatment was effected accordingly. But before the patient was discharged to attend as an out-patient he suddenly lost a quantity of blood from under the dressings, and when he was put under ether the bleeding had to be controlled by compression. It was then found that the axillary artery had been nearly divided by the stab and about two inches higher up another longitudinal wound of the vessel was discovered. Both ends of the artery were secured, the thrombosis being very slight in spite of the length of time that had elapsed, and the patient recovered completely. At the present time (five weeks after the operation) the left radial pulse is absent and the left hand is somewhat cyanosed and colder than the right. The arm can be used as easily as before.

Epidemic Cerebro-spinal Meningitis.

In the eastern parts of Austria an outbreak of cerebro-spinal meningitis has caused great alarm amongst the population. The disease is travelling westwards, one case having been noticed in Vienna. The specific diplococcus, discovered by Fränkel and Weichselbaum, was present in all the cases examined hitherto, especially in the discharge from the nose. Lumbar puncture has not proved very beneficial and the mortality amounts to more than 50 per cent. The neighbouring countries of German Silesia, Bohemia, and Russian Poland are suffering from similar epidemics, which are most likely due to the same source of infection. Prophylactic measures have been enforced throughout the affected districts, especially at railway stations and factories, where the contagion is most liable to be disseminated.

April 17th.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The King Institute of Preventive Medicine at Madras.

THE King Institute of Preventive Medicine at Guindy, a suburb of Madras, has been formally opened. It is named after Lieutenant-Colonel W. G. King, the sanitary commissioner, to whose unremitting efforts for many years the establishment is due. Its origin was brought about by the possible dangers of human lymph in vaccination and the determination of the Government to employ nothing but animal lymph. As bovine lymph is exceedingly sensitive to the heat of the climate it was necessary to render it portable and Lieutenant-Colonel King, who was formerly inspector of vaccination, discovered that animal lymph could be effectively preserved in lanoline. A single and central vaccine institute to serve the needs of the whole Presidency thus came to be required and was sanctioned in 1899. The desirability of having a bacteriological laboratory attached was obvious and this second section was sanctioned in 1902. Further, as it was not advisable for Madras to be entirely dependent on other institutes, a serum section was added in 1903. The Pasteur Institute for Southern India will not form part of the King Institute, as a cooler climate than that of Madras city is considered necessary, and the Pasteur Institute will be established at Coonoor. Without this, however, the King Institute is a very comprehensive undertaking. The supply of sufficient lymph for 150,000 persons every month constitutes probably the largest output in the world. Formerly inoculated animals were driven from village to village and some attempt was made by unskilled persons to preserve the vaccine at petty depôts. The members of the vaccination department will be trained at this institute. The special laboratory at the disposal of the officers of the Indian Medical Service and private practitioners will afford opportunities for research. The bacteriological section examines specimens and issues reports on them and has so far evidently proved that it was wanted, judging from the demands made upon it. The occasion of the opening of the institute was taken advantage of to construct a temporary sanitary and hygienic exhibition but the building itself illustrates many useful sanitary lessons and the underground drainage and a native water latrine are particularly worthy of attention. When in complete working order the King Institute will be the one central place for instruction. Numerous courses of lectures will be arranged and candidates for posts of sanitary inspectors will here get their training.

The High Plague Mortality throughout India.

The plague mortality throughout India is just now at its annual maxima. For the week ending March 11th no less than 45,541 deaths were recorded and for the week ending March 18th 42,088 deaths were reported. The principal figures are: United Provinces, 19,726 deaths, as against 18,938 for the previous week; the Punjab 10,592, as against 11,661; Bengal 7219, as against 7928; and Bombay districts 3224, as against 2656. In both the cities of Calcutta and Bombay the disease is raging virulently. At Rangoon the disease is not only increasing but is spreading to other parts. Plague has broken out on the North-West frontier among the Baluchi tribes and one of the most sensible speeches ever made about plague was delivered in the vernacular to the tribal chiefs. "In order to avoid plague and keep it away from yourselves, your family, and dependents five things are necessary: Firstly, keep yourselves and your houses clean; secondly, avoid going to infected places or receiving persons or things from infected places; thirdly, when plague breaks out or rats begin to die in your house or village go and live in the open; fourthly, do not return to your houses until they have been cleaned and disinfected either by disinfecting medicine or by heating; and fifthly, when plague comes near you get yourselves inoculated."

An X Ray Institute at Dehra Dun.

The Government of India has decided, subject to the sanction of the Secretary of State, to establish an institute at Dehra Dun for use as a centre for the instruction of classes of medical officers and subordinates in the management of x ray apparatus and as a depôt for its storage and repair. The institute will be for the benefit of the community at large as well as for the army.

Nursing Difficulties at the Calcutta Hospitals.

The difficulty of adequate nursing at the hospitals seems to crop up periodically in Calcutta just as it does in Bombay. In the annual report of the Calcutta Institution just published, not only is the staff of nurses at the various hospitals in the city complained of as insufficient but the subscriptions received from the public, and especially from the native population, are said to be very deficient. About 120 nurses are supported by the institution, distributed among the five hospitals. The Government promised to increase its subsidy to Rs. 50,000 if the collections became equal to this amount. Unfortunately they have not. Hospital Sunday in Calcutta only realised about Rs. 5000 (less than £340). The Indian community seem very slow to acknowledge and to recognise the benefits conferred on their fellow countrymen, judging from the very moderate financial support which they contribute. The nursing at the three larger hospitals is superintended by the Clewer Sisters, whose services are gratefully acknowledged by the committee. More nurses are wanted at the Medical College Hospital to carry out the work efficiently but the committee needs further support, especially from the Indian community, before it can see its way to increase the staff. The accommodation for the nursing staff is also quite inadequate. The total expenditure of the institution was Rs.112,560 and there was a loss on working of Rs.2627. There is a provident fund to which the nurses contribute and also a pension fund, both very useful institutions.

The whole question of the nursing at the Calcutta hospitals requires reconsideration.

March 31st.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Protection of Infant Life and Milk-supply.

ONE possible effect of legislation regulating the hours of factory and other employés is an interference with the ordinary delivery of milk. The Women's Liberal League of New South Wales has carried the following motion:—

> [illegible] existing [illegible] trus's [illegible] ent law [illegible]

In a special report to the Sydney Benevolent Society Board Dr. T. Dixson insists on the necessity of a good milk-supply for the infants under its care. The present supply has been found of good quality and fairly uniform in fat contents and it has been possible to keep it at a fairly regular temperature of 40° or 41° F. He recommends the establishment of milk laboratories of the Walker-Gordon type which, in his opinion, would materially help in saving infant life.

Teeth of Australian Children.

The New South Wales Dental Association has arranged with the Education Department with regard to examining the teeth of the children attending the State schools. After examination the children are supplied with a card stating the number of teeth requiring attention. If the parents cannot pay for the necessary work the dental hospital will do it. The children at the Woolloomooloo school were recently tested to the number of 200. The results were fairly satisfactory and there was not nearly so much decay as had been supposed. The girls' teeth were worse than the boys' and showed more evidences of neglect and failure to keep them clean.

Prevention and Treatment of Consumption.

Last October the Sydney City Council passed a code of by-laws dealing with the compulsory notification of consumption. These have now been gazetted and have become operative. The city health officer has issued two circulars, one to householders and the other to medical men, with reference to the by-laws and the prevention and cure of consumption generally. The circular to the profession states that:—

> [illegible] notifying medical [illegible] city health officer or if he fails to express a wish in the contrary sense the city health officer will, as soon as possible after the receipt of the notification, visit the premises occupied by the patient and make inquiries as to the precautions being adopted against the spread of infection, and will issue to the patient's friends what advice he may think desirable on the best means of checking the spread of infection. In all cases [illegible] city health officer.

Dr. Philip Sydney Jones of Sydney recently gave an address to the railway and tramway employés on the prevention and cure of consumption, in which he advocated the isolation of every consumptive. He estimated that 16,000 persons in Australasia suffered from the disease. The sanatorium for consumptives at Macedon, Victoria, is very inadequate to the demands on its accommodation, and owing to the generosity of an anonymous donor is to be added to. The road to the new building was formally opened by the governor last week. Dr. Duncan Talner, in speaking at the opening, said that the success of the institution was unsurpassed by any of its kind in the world.

Possible Contamination of the Water-supply of Sydney.

A new dam is in course of construction at the Cataract River in connexion with the Sydney water-supply. The workmen are camped within the catchment area and within a few minutes' walk of their work. Dr. E. S. Stokes, the recently appointed medical officer of the Sydney Water and Sewerage Board, has made a report to the board, condemning the site and recommending the removal of the camp to a site off the catchment area. He says that heavy rainfall would be certain to cause more or less contamination of the water-supply. Although precautions were taken and the necessary sanitary conveniences were provided at the camp he had ascertained by personal observation that these were not always used. In many instances also the household slops were thrown on the ground. He considered it would be a mere accident if during the course of the work no cases of typhoid were introduced to the camp from outside, and "to retain the camp in its present position is to juggle with fate." The Public Works Department, which is responsible for the camp, states that the site was selected and approved two years ago by the then medical officer to the Water and Sewerage Board, Mr. T. Mailler Kendall. The matter has been referred to the President of the Board of Health for report.

Death from Narcotile given by a Dentist.

A dentist in Sydney administered narcotile for extraction of teeth and the patient died. Post-mortem examination showed congestion of the air passages and a flabby heart. The coroner said that the deceased died from the administration of narcotile. He added that there was nothing in the law to prevent the administration of anæsthetics by dentists but he thought that they should not be administered without an examination by a medical man.

Lunacy Administration in Victoria.

The new Inspector-General of Insane, Dr. W. E. Jones, has arrived in Melbourne and taken up the duties of his position. The new Lunacy Act was passed 15 months ago and the executive council has issued a proclamation bringing the Act into force on March 28th. It provides for the establishment of necessary houses but nothing has been done by the Government to secure places suitable for receiving houses.

State Care of Inebriates.

The Chief Secretary of Victoria has been considering the question of establishing an inebriate institution under the Act passed last session and has received a report from the medical officer to the Melbourne Gaol, Dr. Godfrey, on the subject. The returns for 1904 show that 62 males and 49 females—a total of 111—were convicted three times for drunkenness alone—that is, drunkenness not combined with any other crime. Dr Godfrey, therefore, thinks that accommodation should be provided in an inebriate institution for at least 50 persons. Prisoners under remand and under sentence who were treated in the gaol hospital last year for alcoholism numbered 401 males and 103 females—a total of 504 Of these, 42 males and seven females were in the most acute condition with delirium tremens, requiring mechanical restriction. Over 450 were in various stages of acute or chronic alcoholism, varying from the initial stage of delirium tremens to the subacute form. The average period of hospital treatment was eight days. The number of those admitted to the hospital three times or more for delirium tremens during the year was: males, 40; females, 34, total, 74. There had been admitted to the gaol, of all types, about 80 male and 70 female habitual drunkards during the year. Under a rigid application of the proposed law that three or more convictions should constitute habitual drunkenness nearly all of these would be liable to committal to the inebriate institution during the first part of its operation, but as a number of these are more or less criminals or vagrants it is probable that a proportion will be imprisoned at various times on other charges Therefore, about 30 males and 25 females would probably be the number to provide for.

March 15th.

Obituary.

THOMAS MORTON, M.D. LOND., M.R.C.S. ENG., L.S.A.

Dr. Thomas Morton died at his residence, 15, Greville-road, Kilburn, London, N.W., on March 27th after a short illness. He was born at Holbeach in Lincolnshire in November, 1836, his father being the Rev. James Morton, vicar of Holbeach and prebendary of Lincoln. In 1854 he entered at Queens' College, Cambridge, but in the following year he received an appointment as a clerk in the office of the secretary of the General Post Office. After three years spent in this service he resolved to enter the medical profession. He accordingly matriculated at the University of London and entered at King's College in 1858, gaining a Warneford entrance scholarship. In 1862 he obtained the diplomas of M.R.C.S. Eng. and L.S.A. and after a visit to the Paris hospitals he graduated as M.B. Lond. later in the same year, taking the M.D. degree in 1865. In 1863 he commenced practice in Kilburn and in the following year married a daughter of the late Mr. William J. Thoms, F.S.A., librarian of the House of Lords and originator of *Notes and Queries*. At an early period in his career he became surgeon to the Kilburn Dispensary and while holding this appointment he published in the *Obstetrical Journal of Great Britain and Ireland* several cases of puerperal septicæmia successfully treated by purgation with calomel combined with Dover's powder or compound extract of colocynth. This system of eliminating toxic material was anticipatory of more recent practice by at least one eminent gynæcologist now deceased. Dr. Morton was one of the founders of the Kilburn Provident Medical Institute which came into existence about 1874 and the services which he rendered during his long connexion with it were recognised by his being elected chairman and consulting medical officer. From the time of his joining the Church of England Temperance Society in 1875 he became an active worker in the cause of temperance. He was intimately associated with the late Dr. Norman Kerr in the temperance movement and was a member of the Society for the Study of Inebriety from its foundation in 1884 until his death. He was secretary to the committee appointed to inquire into the relation of heredity to drunkenness and the *résumé* which he made of the committee's proceedings was a model of precision and literary grace. Rarely absent from the meetings of the society, when he rose to speak—as he frequently did—his fine presence and the modesty and earnestness of his bearing at once commanded the attention of his audience. Though an ardent advocate of temperance Dr. Morton was wholly unaggressive; he was a man who worked unobtrusively for good, one whom but to know was to honour. His good influence will long outlast him.

Sir William Broadbent writes to us as follows: "I have known Dr. Morton almost from the time of my coming to London and his character always commanded my respect and regard in a very high degree. He seemed to realise the type of the family medical man. He was thorough in his investigation, calm in manner, kind, sympathetic, and above all trustworthy and judicious, a friend in whom his patients could safely confide. A convinced total abstainer he was moderate in the advocacy of his views, but exercised great personal influence in the direction of temperance. If he had a visible fault it was modesty, but the members of the Harveian Society will remember the quiet dignity with which he filled the office of President."

EDWIN THOMAS TRUMAN, M.R.C.S. ENG.

Mr. Edwin Thomas Truman, who died on April 8th at the age of 86 years, held for over half a century the position of dentist to the Royal Household, having been appointed on Feb. 28th, 1855. Mr. Truman's name was, however, more widely known in connexion with matters outside the immediate practice of his profession. The first Atlantic cable in 1858 failed owing to want of perfect and durable insulation, due to the fact that gutta-percha used as the protective covering could not at that time be thoroughly purified. Mr. Truman, who had been experimenting with gutta-percha for ten years in connexion with his professional work, discovered a method by which gutta-percha could be prepared in any quantity by purely mechanical means without injury to the material. The patent of the discovery was disposed of to the gutta-percha company who made the cable for the Atlantic Telegraph Company, and nearly all cables subsequently laid have been covered with gutta-percha purified by Mr. Truman's process. In addition to being an inventor Mr. Truman was probably the oldest book-collector in London at the time of his death, having started his hobby at the age of 15 years. He was specially interested in Cruikshank's works, of which he formed by far the finest collection in existence and he was perfectly familiar with every detail of his subject. He also possessed a fine collection of old historical portraits of English celebrities and of coloured prints, caricatures, and drawings

DAVID SMITH, M.D. ST. AND., M.R.C.S. ENG.
